How psychoactive drugs shape human culture: a multi-disciplinary perspective

Abstract

Psychoactive drug use occurs in essentially all human societies. A range of disciplines contribute to our understanding of the influence of drugs upon the human world. For example pharmacology and neuroscience analyse biological responses to drugs, sociology examines social influences upon people's decisions to use drugs, and anthropology provides rich accounts of use across a variety of cultural contexts. This article reviews work from multiple disciplines to illustrate that drugs influence aspects of culture from social life to religion, politics to trade, while acting as enablers of cultural change throughout human history. This broad view is valuable at a time when the influence not only of traditional drugs but a growing armoury of novel drugs is felt and debated.

1 Introduction

Psychoactive drug use occurs in essentially all human societies (Withington, 2014; Thakker, 2013). The use of mind-altering substances has been central to a range of human phenomena from shamanic rituals to village pubs to youth counter-cultures (Shortall, 2014). This paper argues that drugs are not merely components of, but rather significant influences upon culture.

It is a remarkable thing, easily overlooked because it is so commonplace, that a very small dose of a chemical can change the way someone thinks and feels. Furthermore, this subjective change can be so compelling that a desire to repeatedly experience it motivates individuals and groups to carry out complex plans that play out over timescales ranging from hours to decades. A range of research disciplines contribute to our understanding of the influence of drugs upon the human world. A major focus has been on why people take drugs and what happens to them when they do (Withington, 2014). While effects upon individuals are a focus of biomedical research (Schultes, 1969), disciplines such as anthropology, evolutionary biology and ethics contribute to an understanding of the broader impact of drugs (Guerra-Doce, 2015). Each of these addresses a critical part of what Withington calls “the cumulative importance of intoxication”; yet none can alone address the complete picture.

1.1 *Material and Method*

This article reviews work from multiple disciplines to shed light on the role of drugs in culture and cultural change. Material was drawn from key journals, books and annual reviews in relevant disciplines, as well as secondary sources that take broader cultural or historical views, with the intention of providing a concise but thorough overview of current thought. This broad view is valuable at a time when societies debate the influence not only of traditional drugs but a growing armoury of novel drugs. The sections following review categories by which we understand drugs and culture, the ubiquity and variety of drug use, the ways in which drug use has influenced culture and behaviour, and syntheses of the role of drug use in the larger human story.

2 Categories and definitions

2.1 *Psychoactive drugs*

Drugs are substances exogenous to the body which, when ingested, influence biological function by mimicking the action of neurotransmitters upon neurons (Kenakin, 2004). This paper is concerned with psychoactive drugs – those that influence brain functions such as emotion, thought and behaviour.

Sherratt (1995a), introducing the trail-blazing collection of anthropological essays on drugs *Consuming Habits* (Goodman et al., 1995), argued that when analysing drug use it is important first to clarify terminology, since the language of drugs is morally charged and carries legal, ethical and referential meanings that vary in time and space (see also Withington, 2014 p. 14). Biological definitions of the term *drug* disregard a substance’s legal status and the purposes for which it is administered. However, legal status and purpose of use are incorporated into the semantics of informal language. The Oxford English Dictionary lists both a scientific definition

of “drug” and this vernacular one: “A substance taken for its narcotic or stimulant effects, often illegally.” Hugh-Jones (2007) noted that the concept of drug depends on: “a specific set of rules, norms and conventions concerning the appropriate ways in which these substances are to be distributed and consumed.” Thus non-medical drug use is often called “abuse”, regardless of whether it is problematic, or “recreational” when the purpose for using might well be work-related (cf. Glantz, 2013).

The distinction between medical and recreational use is ancient and cross-cultural (Courtwright 2001, p. 89); however “medical” drugs are frequently abused, and most illegal “drugs of abuse” have at some time or place been used medically - heroin and cannabis are examples. The concept of *drug* is often tied to the phenomenon of *addiction*; yet not all illegal drugs are addictive (e.g. lysergic acid diethylamide, LSD), some legal drugs *are* addictive (e.g. nicotine), and the harm to society from legal drugs outweighs that caused by illegal drugs (Gowing, 2014). History shows that the legality of a drug tends to be somewhat arbitrary and dynamic: Kushner (2010) noted that it depends more upon “social norms and power relationships” than on pharmacological properties. Medical, religious and recreational use has often been intertwined. Thousands of psychoactive plants have been used in traditional medicines in every area of the globe (and significant research is devoted to exploring their potential to yield new drugs). As drugs cross borders, the conceptual boundaries between legal and illegal, drug and medicine can shift, as demonstrated for example in the widespread prescription of antidepressants by unlicensed doctors in India (Ecks and Basu, 2014).

Newly-engineered pharmaceuticals such as those described elsewhere in this special issue can be difficult to categorize within mainstream schemas of legality, addictiveness and purpose of use. Designer drugs emulate the effects of traditional illegal drugs but are made structurally different in order to avoid prosecution. Authors such as DeGrandpre (2006) have highlighted the “confusion and chaos” of our ethical thinking around drugs: as one drug becomes restricted, pharmacologically equivalent, not-yet-illegal drugs are rapidly devised. There is debate about the ethical status of emerging approaches to mental and physical enhancement using novel and existing psychiatric medicines.

Evolution in legal, political and scientific thought, consumer preference, commercial activity, colonialism and globalization have impacted how societies categorize and understand drugs. For this reason Sherratt (1995a) felt that “drug” was too imprecise for academic discourse and preferred the neutral term “psychoactive substance”. Terms such as “psychotropic” and “psychopharmaceutical” are evocative and precise, but unwieldy. A recent issue of the *Journal of Ethnopharmacology* (Lo et al., 2015) discusses the fuzzy boundary between food and drugs, noting that spices, which sit astride this boundary (see Bourgeois et al., 2014), have inspired global commerce comparable to the drug trade. When drugs are eaten with food, their effects on mood can be confused with nutritional benefits (Hagen et al., 2013). Thus Jankowiak and Bradburd (1996) used the term “drug foods” to refer to alcohol, coffee and chocolate. Courtwright (2001) acknowledged the complex semantics of the word “drug” but chose to use this word for brevity, intending the term to encompass all psychoactive substances whether legal or illegal, natural or artificial, and used for medical or recreational purposes. Using this familiar if loaded word helps to reinforce the common properties that all psychoactive substances possess while undermining artificial boundaries. This paper follows Courtwright in referring to “drugs”, and emphasizing that to fully understand the impact of these substances, one ought not to exclude arbitrarily-defined subsets.

2.2 Drug use

In elaborating influences upon culture, one should also define *drug use* as broadly as possible. In pharmacology, psychology, sociology and some anthropology, the focus of drug research is often on compulsive use or addiction: “putative enslavement to a substance or activity” (Weinberg, 2011). Compulsive use can have devastating consequences for users, family, friends and society if the drug, its vehicle or means of administration have negative effects on health, or the cost of regular administration is so high that the user is forced to adopt illegal, unhealthy or stigmatized methods of making money. Though drug use is an ancient phenomenon, serious addiction is a modern one, becoming widespread with the distillation of spirits, the isolation of active ingredients such as morphine and cocaine, the invention of effective means of administration such as the hypodermic syringe and the cigarette, and the globalization of traditional, regional drug cultures (Westermeyer, 2013). Addiction involves multiple processes operating at different levels of organization, and a large multi-disciplinary body of work debates how the phenomenon should be understood: for example whether it is a disease or conversely whether the disease model diverts too much attention from environmental and social factors (Skewes and Gonzalez, 2013; Garriott and Raikhel, 2015). Discourse on addiction is prominent and shaped by a range of medical, legal, scientific and political actors (Courtwright, 2012). Yet as Muller and Schumann (2011) point out, addiction represents only a small fraction of total drug use. Drugs have played “multiple, often positive social roles—as markers of identity, occasions of conviviality, talismans of faith—that had little to do with addiction” (Courtwright, 2012 p.489). The vast majority of people make routine use of “mundane drugs” (Sullivan and Hagen, 2002) without experiencing major addiction.

With the focus of attention on problematic use by a minority, is it possible we are overlooking interesting effects that accrue from mundane drug use by the majority? Noting that as much as a quarter of the US adult population may be taking psychopharmaceutical medication (Jenkins, 2010), ethicists such as Levy et al. (2014) have asked whether widespread drug use might be influencing moral behaviour in subtle ways, while authors such as Smail (2007) and Courtwright (2001) have explored the socio-political implications of wide-scale drug use; these perspectives are discussed below.

2.3 Culture

Which phenomena might be shaped by drugs? Culture is a key concept in several disciplines, and there is debate over what precisely it comprises. Harris (1968) divided culture into levels: infrastructure (how people satisfy biological needs), structure (the domestic and political economy) and superstructure (religious, intellectual and artistic endeavours). Kehoe (2013) refers to a set of patterned behaviour associated with a particular group, and one can speak of “a” culture, defined by the OED as: “the ideas, customs, and social behaviour of a particular people or society”. Thus, culture varies in time and space and can refer to material artefacts, learned individual and social behaviours, customs, rituals and religion, artistic practices, economic behaviour and socio-political structures.

Humans transmit culture down the generations via social learning. The analogy with genetic transmission has led to theories of gene-culture co-evolution (Richerson et al., 2010). Kitayama and Uskul (2011) speak of culture as being “embrained”, meaning that it is reflected in neural patterns, requires brains for existence and transmission, and is constrained by biology and psychology. Lende and Downey (2012) speak of the “encultured brain” and propose a unification of anthropology, psychology and neuroscience to explore interactions between brain and culture.

Since culture reflects beliefs, desires, emotions and behaviours, to the extent that drugs influence these subjective experiences they should influence their expression as culture. The next two sections marshal evidence for this model by surveying the range of drugs in use and the mechanisms by which they influence behaviour and culture.

3 Variety and ubiquity of drug use

The majority of contemporary humans regularly use drugs (Anderson, 2006; Kennedy, 2014), and drug use figures prominently in all known cultures going back to antiquity (Sherratt, 1995a; Withington, 2014). Quantum increases in variety and usage occurred with the adoption of farming (Crocq, 2007; Wadley and Hayden, 2015), the colonization of the New World and industrialization (Goodman, 1995; Courtwright, 2001), and with the development of drug synthesis techniques (Courtwright, 2001; Levy et al., 2014).

Drugs were used in pre-agricultural, foraging societies (Saniotis, 2010:481; Thomas, 2003) though primarily in medicine (Guthrie and Ho-Yen, 2011) and ritual (VanPool, 2009). Many traditional plant extracts induce hallucinations or trance states and have been central to the practice of religion in forager societies. Hallucinogens such as N,N-dimethyltryptamine (DMT), psilocin and mescaline allow shamans to enter trance states (Merlin, 2003, p. 295; VanPool, 2009) and were used from thousands of years ago in Central Asia, Central America and the south-western United States (Crocq, 2007). The powerful effects of hallucinogens deter widespread consumption, so that use among foragers is restricted to religious specialists. Plant-derived stimulants and sedatives such as caffeine and khat (Africa), cocaine (South America), kava and betel (Asia-Pacific) and nicotine (America and Australia) have been used by traditional societies during social interaction, to increase productivity and to relieve boredom, fatigue and hunger. Foraging peoples have provided to hunting dogs stimulants to improve their attention and work rate, and hallucinogens, though it is uncertain whether the latter represents magical practice or improves the dog's ability to detect prey via heightened senses (Bennett, 2015). Thousands of plant species have been used in traditional medicines in every area of the globe. A large research effort, such as that published in the *Journal of Ethnopharmacology*, is devoted to identifying traditional herbal drugs, testing their effects in the laboratory, and exploring their potential for modern medicine. Many traditional remedies are psychoactive, used for example to relieve pain or melancholy, such as the opioid-like kratom leaf discussed elsewhere in this issue.

With the adoption of farming, the focus of production and consumption shifted from perception-altering to mood-altering drugs (Merlin, 2003; Smail, 2007). Farming enabled larger quantities of drugs to be reliably produced and regularly consumed (Saniotis, 2010; Sullivan and Hagen, 2002). Old drugs were domesticated and cultivated (e.g. tobacco) and new ones were invented (e.g. beer and wine). Archaeobotanical evidence for psychoactive plant use increases significantly with the Neolithic transition (Guerra-Doca, 2015). Early Asian farmers produced alcohol, while Americans produced alcohol, coca, tobacco, and cacao. In the areas to which farming spread, Europeans added opium and cannabis to the crop complex received from the Near East, while in India farmers grew grains for alcohol, and in Africa coffee and kola became major trade items (see table 1 in Wadley and Hayden, 2015).

Most of the drugs domesticated by Neolithic farmers are still in widespread use. The past half-millennium has seen the globalization and purification of traditional drugs (e.g. cocaine, morphine, alcoholic spirits) and the invention of new ones (e.g. amphetamines, psychiatric medicines) along with massive increases in scales of production and distribution (Courtwright, 2001). The remainder of this section surveys the range of drugs in common use.

3.1 The “big three”: alcohol, nicotine and caffeine

Alcohol, nicotine and caffeine – Courtwright’s (2001) “big three” - have enjoyed widespread use as well as social and legal approval in so many cultures (Crocq, 2007) that they are more-or-less immune to prohibition, with alcohol often obtainable even where religion forbids it (Courtwright, 2001). Yet legal drugs create significant public health concerns, with a recent report showing a quarter-billion people worldwide with alcohol use disorders and a billion smoking tobacco (Gowing, 2014).

Alcohol may have been ingested by early humans eating fermented fruit, a behaviour that may have evolved in primates (Dudley, 2002). However alcohol was probably not used in appreciable amounts prior to farming. Alcohol production is a hallmark of Neolithic transitions around the world: first appearing from 12,000 years ago among cereal farmers in the Middle East (Hayden et al., 2012), China (McGovern et al., 2004), Central America (Smalley and Blake, 2003), Incan South America (Staller, 2009), and India (Fuller, 2005). Alcohol cannot be obtained by simple extraction but is the product of a complex technological and biochemical process (Hayden et al., 2012) requiring significant organization and a sophisticated material culture. Part of the impact of alcohol on culture is therefore tangible in the form of brewing, consumption and storage equipment, such as the vast quantities of amphorae discovered in Bronze Age and especially Mediterranean maritime archaeology. While most early alcohol was probably brewed in beer, wine from grapes and other fruit was a staple by the time of the Greco-Roman civilization (Sherratt, 1995b). Plants other than cereals and grapes have been fermented: for example African societies used cereals, honey, plantain and palm trees (Nugent, 2014), while Soukand et al. (2015) describe over a hundred species fermented in Eastern Europe, including products comprising both food and drugs such as a traditional Estonian gruel prepared from rye, potatoes, milk, poppy and cannabis.

Alcohol has had an enormous impact on social and religious practices around the world (Sherratt, 1995b). Guerra-Doca (2015) discusses its use in rituals and feasts in prehistoric Eurasia. It played a major role in public and private life in most of the major early civilizations, where it was consumed at religious, political and social events (Jennings et al., 2005). Public alcohol consumption helps reinforce social relations and political power (Guerra-Doca, 2015; Dietler, 1990; Hayden, 2014). It is so deeply embedded in modern Western culture that it has survived the “challenges of other, more stimulating drinks acquired through the colonial experience” (Sherratt, 1995a) as well as attempts to prohibit its use. In a great many societies alcohol has served to enhance solidarity and social life (see below), recognition of which has placed anthropologists at odds with medical researchers who are more likely to focus on ill-effects (Singer, 2012).

Nicotine is an alkaloid found naturally in tobacco plants (genus *Nicotiana*) and a few other species. It is habit-forming (Pontieri et al., 1996) and has multiple effects including relaxation, stimulation and pain relief (depending on dose), enhanced memory and concentration, reduction of anxiety, and psychological reward. Tobacco has been used by American and Australian foragers and was domesticated in tropical America as early as 4,000 years ago (Rafferty, 2006) where it was used in rituals, as medicine, and for trade and recreation (Wilbert, 1979). While tobacco was probably originally used by shamans, with cultivation its use became more democratized (von Gernet, 1995). Tobacco spread throughout the Americas and was probably introduced into North America along with maize by at least two thousand years ago (Rafferty, 2006). Pituri, a source of nicotine native to Australia, was a major trade good in pre-colonial Australia (Silcock et al., 2012).

After the discovery by Europeans of the New World in the 15th century, tobacco became a major driver of Atlantic colonization and trade (Price, 1995). In response to increasing

popularity, attempts were made in the 16th century to grow tobacco in Europe. Tobacco was the economic lifeline of the English colony of Virginia, inspiring other European countries to found tobacco colonies. European traders sold it to native fur trappers in North America; thus tobacco became an integral part of trans-Atlantic commerce (Van Geret, 1995). Along with other New World drugs, the use of tobacco skyrocketed in Europe, helping to create a new kind of economy based on mass consumerism (Goodman, 1995). Its enormous popularity in the 17th century allowed European governments to increase their tax take, so that governments became financially reliant on mass drug use. Debates took place in Europe over whether tobacco should be grown at home or in the colonies, and how it should be taxed in order to maximize revenue (Price, 1995). When introduced to Islamic regions there was debate over whether tobacco (along with coffee) was compatible with religious teaching (Matthee, 2014). Though nicotine consumption is associated with addiction and disease, research indicates that tobacco use protects against parasite infestation in central Africa (Roulette et al., 2014) and that individual users modulate intake in response to infestation, demonstrating the possibility that drug use can be adaptive (Sullivan and Hagen, 2002).

Caffeine is a psychoactive alkaloid obtained from the coffee, tea, cocoa, kola and guarana plants and is currently the world's most popular drug. More than 85% of Americans make significant use of it (Weinberg, 2000). It is a stimulant, can reduce anxiety and depression (Pechlivanova et al., 2012), and may be an effective treatment for attention deficit hyperactivity disorder (ADHD) (Ioannidis, 2014). Caffeine enhances performance on several cognitive tasks – though in some cases only for extroverts (Smith, 2013).

Caffeine-yielding plants are native to a number of regions. Coffee was first exploited in Ethiopia 1500 years ago (Anthony et al., 2002) while tea was used in China at least 2,000 years ago (Chen, 2005). Fermented cacao (which also contains the pharmacologically similar alkaloid theobromine) was in use over 2000 years ago in central America (Powis et al., 2002) and may have enabled Olmec societies to expand trade and power in Mesoamerica. Subsequently chocolate was used in social and ritual settings by the Mayans and served as a currency and elite drink for the Aztecs. A major source of caffeine in Africa is the kola nut, which has been cultivated and traded around Sudan for 1,000 years (Lovejoy, 1995). With the Islamic proscription of alcohol, kola became a prestige good and a component of various cultural practices. It was given to dinner guests, used for official gifts, and distributed by would-be “big men” to curry political favour. It was used as a courtship gift and believed to induce sexual desire in women; given to labourers as compensation and to combat fatigue, and to soldiers to increase bravery before battle (Lovejoy, 1995). Kola became the basis of European and American tonic drinks, though most manufacturers now source their caffeine elsewhere.

The introduction of caffeine to eighteenth century Europe impacted material culture and domestic and public space (Smith, 1995). Caffeinated drinks replaced the traditional breakfast of porridge and alcohol (Goodman, 1995) and helped shift the focus of public life to cafés, with a concomitant increase in political activity (Smith, 1995). Coffee houses provided a forum to discuss politics and art and helped to spread ideas across class boundaries (Courtwright 2001, p. 101). Chocolate grew in popularity in 18th century Europe and became deeply embedded in European culture (Goodman, 1995).

3.2 Drugs that currently are widely proscribed

Cannabis is probably native to central Asia (Clarke and Merlin, 2013). It was one of the earliest drugs used in China and India (Merlin, 2003) and is mentioned in ancient Indian texts. It spread via the Eurasian steppes to Eastern Europe soon after initial domestication (Rudgley, 1995). The primary psychoactive alkaloid is tetrahydrocannabinol (THC), but cannabis also

yields food (from oils and starches in the seeds) and hemp (from the stems) used in textiles and paper (Clarke and Merlin, 2013). Cannabis creates euphoria, reduces anxiety and pain and is mildly hallucinogenic (Ashton, 2001). It has featured in religions throughout Europe and Asia including Hindu, Scythian, Zoroastrian and Chinese shaman cultures from over 2000 years ago (Clarke and Merlin, 2013). Cannabis was a major crop in the 19th century British empire (Mills, 1995), where Indian labourers smoked cannabis at work, with visitors at home, and at religious and cultural ceremonies. Imperial labourers took cannabis to South Africa and probably the West Indies (Mills, 1995). Cannabis was banned but did not disappear after the Muslim conquest of Egypt in the 14th century; a later ban by the British led to the creation of an international smuggling route which persists today (Mills, 1995).

Cocaine derives from the coca plant, domesticated in the Andes where it was used for millennia to mask fatigue, hunger and pain (Plowman, 1984) and where millions still use it daily (Burchard et al., 1992). There is evidence of coca use as early as 8,000 years ago in northern Peru, where it “was a feature of the rise of agriculture and social complexity in the region” (Dillehay et al., 2010). Coca was a status marker for Incans and was accorded religious significance (Plowman, 1984). After the active ingredient cocaine was isolated it became a popular stimulant and local anaesthetic in Europe and the United States, and was mixed with wine and kola to create popular tonic drinks. Courtwright (1995) describes cocaine epidemics in the late 19th and late 20th century USA. It was used by 19th century labourers until perceptions of its addictive potential and ability to engender crime and incivility caused its popularity to decline, until it was eventually banned. Its popularity revived in the 1980s, as new trading routes and forms of administration were pioneered (Courtwright, 1995).

Amphetamines are synthetic drugs that, like cocaine, stimulate dopamine release to create a feeling of energy. They are used under prescription to treat attention deficit disorder and without prescription to enhance wakefulness, mental and physical performance, and sociability. Originally sold as cold medicine in the early 20th century, amphetamines were soon used by students and military personnel and then prescribed widely for a range of psychological conditions, before their addiction potential saw them progressively restricted from the 1970s on (Courtwright, 2001 p. 81). Shift workers, truck drivers and soldiers take amphetamines for alertness and improved work output, while up to a third of university students take them to improve study performance (Petersen, 2015). Amphetamines have high addiction potential and sustained use can induce psychosis (Fulde and Forster, 2015).

Plant-based **hallucinogens** such as psilocybin, mescaline and DMT have been employed for spiritual and ceremonial purposes in forager societies (VanPool, 2009). Artificial hallucinogens such as LSD were synthesized in the mid-20th century. They were initially used in psychological research and treatment, but after promotion by public figures such as Aldous Huxley and Timothy Leary, became an iconic drug of choice for youth subcultures (who were partly inspired by Native American use of psilocybin), after which they became illegal in most countries. There were political aspects to the countercultural adoption of LSD, with some viewing it as a revolutionary tool, and charismatic leaders controlling followers via their drug supply (Shortall, 2014). Subjective experiences include hallucinations, euphoria and intense spiritual or religious feelings, leading to some naming these drugs “entheogens”, however if the user’s mindset and context are inappropriate such experiences can transform into anxiety and psychotic-like episodes (Griffiths et al., 2006). Currently there is renewed interest in hallucinogens as a treatment for anxiety and depression (Majic et al., 2015; Hendricks, 2015) and palliative care (Grob et al., 2013).

Opiates are derived from the opium poppy, which is native to Mediterranean Europe and was probably the first plant added to the Neolithic crop complex imported from the Levant (Zapata, 2004; Guerra-Doce, 2015). Poppies, cereals, and pulses formed the plant assemblages

of the first farmers in Italy (Merlin, 2003), and opioids have been found in the bones of Neolithic miners and at burial sites in Spain (Zapata, 2004). Opium became widely used around the world medicinally and recreationally (Levinthal, 1988), especially in the Islamic world where it was an alternative to alcohol (Matthee, 2014) and in China and diaspora countries including the United States (Courtwright, 2001). The active ingredient morphine was isolated in the early 19th century, and the variant diamorphine (heroin) synthesized in the late 19th century; both substances enjoyed success as commercial medicines until their addictive power was recognized and legal proscription began in the 20th century. Opiates have been associated with subcultures and avant-garde artists and have inspired significant literature, film and music (see e.g. Hussey, 2013). They have been prescribed for almost every medical condition. The use of legal prescription opiates is burgeoning in Western cultures due to increased incidence of chronic pain and palliative care as well as illicit use, all of which can lead to term long-term dependence (Berterame et al., 2016).

3.3 Drugs traditionally used outside the Western context

While several drugs discovered during European colonialism were successfully exported back to Europe, many other regionally popular drugs have not been globally adopted, mainly due to aesthetic and logistical problems such as short shelf-life (Courtwright, 2001). At the same time, a number of traditional herbal drugs, once widely used in Europe, lost their currency with the rising popularity of New World drugs.

Betel is a stimulant produced from the nut of the areca palm, the leaf of the betel pepper, and lime (Norton, 1998). Betel chewing was well established in China and India 2000 years ago (Norton, 1998) and forms part of daily life for 200 million people in coastal areas of the Western Pacific and South Asia. Globally only nicotine, alcohol and caffeine are more widely used (Norton, 1998). The betel nut features in origin myths and has cosmological significance, and is very important to the economy of Papua New Guinea (Hirsch, 1995). It is used to enhance work and social activities, and given symbolically to guests and at important occasions such as marriages and funerals.

Khat is a stimulant/relaxant used traditionally in the horn of Africa and Yemen, and now popular in neighbouring countries and among the African diaspora in Europe and North America. Traditional khat use is highly routinized, part of daily work routines and social gatherings, negotiations, marriages and funerals, and religious ceremonies (Klein and Beckerleg, 1995). Before air travel it was difficult to transport khat over long distances because the leaves degrade quickly, but khat is now used in diaspora cultures in Europe (Bongard and Nakajima, 2015), leading to concerns about abuse (Odenwald et al., 2010).

Kratom has opioid-like properties and has been chewed, smoked and drunk in South-East Asia for thousands of years to enhance energy and mood, dull pain, to remedy various medical problems including opiate addiction, to enhance sexual performance, and to prevent exhaustion and hunger in workers (Hassan et al., 2013). It has recently become available for purchase over the Internet and is becoming a popular drug globally, inspiring research into its potential for good or harm (Stolt et al., 2014 and papers in this special issue).

3.4 Sugar and food addiction

Humans eat sweet, energy-dense foods in response to depression, stress and negative affect (Gibson, 2012). “Comfort foods” (Dube et al., 2005) induce “a psychologically comfortable and pleasurable state” (Wansink et al., 2003) and may lead to food addiction (Ifland et al., 2009; Davis et al., 2014; Volkow and Wise, 2005). Sucrose has come to be seen as having

drug-like properties: it acts as an analgesic (Blass et al., 1987), reduces stress (Ulrich-Lai et al., 2010) and future-discounting (Wang and Dvorak, 2010), and repeated consumption leads to tolerance and withdrawal (Johnson and Kenny, 2010). High-fructose corn syrup is added to many foods and may be more hedonic and addictive than sucrose (Leri and Levy, 2015). Compulsive eating is associated with obesity, depression and hyperactivity (Davis et al., 2011) and supports a global industry that satiates the craving (Volkow and Wise, 2005).

Humans are drawn to sweet tastes probably because in ancestral environments they signalled high nutritional value (Lenoir et al., 2007). Preference for sweetness has driven a desire for sucrose-yielding plants since ancient times. Sugar cane appears to have been first used at least 6,000 years ago in New Guinea (Daniels and Daniels, 1993; Bellwood, 2011). Its cultivation and use spread throughout Asia and the Islamic world into Europe and thence via colonization to tropical Africa and America (Grivet et al., 2004). With the development of crystallization and large-scale plantations, sugar became widely available to non-elites. During the 19th century British working class people began using it to sweeten tea, coffee and chocolate: imported drugs whose use was also rapidly democratizing (Courtwright, 2001). Demand became so great that sugar, like tobacco, was a major driver of colonization and trade.

3.5 Medicines and designer drugs

Plant-derived drugs have been used for millennia to counter aversive mental states. Recently a range of new drugs including antipsychotics, antidepressants, anxiolytics, sedatives, stimulants and painkillers have been synthesized for the treatment of mental health conditions. Many of these are also (ab)used outside of a prescription framework (Petersen, 2015) for purposes that blur the boundary between medicine and enhancement (Pieters and Snelders, 2009). Psychiatric drugs share with drugs of abuse the ability to induce desirable mental states, and can influence behavioural phenomena as varied as motivation, emotion, social functioning, romantic love (Kirmayer and Raikhel, 2009), agency, the sense of being in or under control, and the perceived value of others (Jenkins, 2010). The ability to manipulate molecular structures, along with ubiquitous e-commerce, has given rise to industries that produce new drugs with desirable psychoactive properties, variants on traditional drugs with improved properties, and analogues of traditional drugs designed to evade legal restrictions. These industries continuously augment a “tool kit” (Muller and Schumann, 2011) that affords users ever finer control over their mental states (Farah et al., 2004).

Popular designer drugs include the dissociatives methoxetamine and ketamine, stimulants alpha-pyrrolidinopentiphenone (alpha-PVP, “flakka”, “gravel”) and methylenedioxypyrovalerone (MDVP, “bath salts”), and the empathogen 3,4-methylenedioxymethamphetamine (MDMA, “ecstasy”). MDMA increases sociability, face-trustworthiness, cooperative behaviour (Stewart et al., 2014), financial generosity (Kirkpatrick, 2015) and the use of social and sexual words (Baggott, 2015), while making identification of social threat less accurate (Bedi et al., 2010). Party drugs are the basis of a global youth culture which sees groups gather to dance and take drugs (Joe-Laidler et al., 2014).

Novel cognitive enhancers improve psychological functions such as memory, attention and work output (as do traditional drugs – see Kirmayer and Raikhel, 2009). Synthetic stimulants such as methylphenidate (“Ritalin”) and amphetamine (e.g. “Adderall”) are prescribed for attention deficit but also used illicitly by athletes for better performance and by university students to make study more effective and enjoyable (Petersen, 2015). Enhancement is distinct from medicine in that the intention is not to fix a deficit but to enhance normal functioning. Ethicists have begun to address the prospect of *moral* enhancement by new drugs

(e.g. Ilieva, 2015 and see below), while anthropologists ask whether what it means to be human is being transformed by designer drugs (Jenkins, 2010).

4 Mechanisms of influence on culture

The previous section demonstrated the ubiquity, range, and deep history of psychoactive drug use in human cultures. A broad range of ethnographic and archaeological writing (e.g. in Goodman et al., 1995) has demonstrated that drugs are integral components of culture; fundamental to religion and social life and the formation of cultural identities, civilizations, and the world economy. Withington (2014) lists three primary influences of drugs on culture: the association of intoxication with cultural production, the prominence of drugs in popular discourse, and the economic importance of drug taxation. This section reviews evidence for the influence of drugs on behavioural, material and structural aspects of culture.

4.1 Motivation to engage in production and consumption

Many psychoactive drugs are intrinsically rewarding, inducing desirable states such as euphoria (Nesse and Berridge, 1997) and sociability (Velea and Hautefeuille, 2007), attenuating unwanted states like stress, fatigue and low mood (Morgan et al., 2013; Pickard, 2012), or enhancing mental and physical functioning (Muller and Schumann, 2011; Kirmayer and Raikhel, 2009). These perceived benefits create a powerful motivation to engage in the production and consumption of drugs; activities which for millennia have represented a significant portion of economic and cultural activity.

Drugs with the potential for abuse, such as many of those described in the previous section, directly activate brain pathways that regulate appetitive anticipation and consummatory hedonia (Berridge and Robinson, 1998; Blum et al., 2012). This can induce cravings for repeated use (Robinson and Berridge, 1993) and lead to tolerance and addiction (Koob and Le Moal, 2001). Their salience is perhaps most visible in drug subcultures (Brake, 1980) which form when people share understandings and practices around drug-taking and drug procurement, or a need for security, self-respect and profit (Singer, 2012; Karandinos et al., 2014). Drug subcultures occur in populations as varied as addicts, party-goers, hippies, artists, and criminal gangs (Moore, 2004; Brake, 1980). Outlaw subcultures can incorporate status hierarchies that are “brutally enforced” (Muehlmann, 2013) with weapons and personnel funded by drug commerce. Drug dealers can become defacto leaders and protectors of their community (Karandinos et al., 2014). Karandinos explains this political phenomenon in terms of Marx’s “primitive accumulation” theory of the origins of class distinctions. But controlling the supply of a widely-desired drug does not confer power only in outlaw subcultures; rather it has been a prized privilege of governments, military leaders and colonists throughout history. Thus the distinction between subculture and mainstream, like the distinction between addiction and mundane use, is blurred.

Different disciplines understand compulsive drug use by focussing on phenomena that emerge at different levels of organisation. Pharmacologists have built physiological models of addiction involving, for example, dysregulation of a common reward centre (Korpi et al., 2015) and impairment of brain plasticity (Kasanetz et al., 2010). Such models hold out the promise of a pharmacotherapy for addiction (Koob and Mason, 2016) but are challenged by the fact that not everyone exposed to drugs becomes addicted (Volkow et al., 2012). Critics have debated the value of brain disease models and emphasized the complex biosocial (Nutt et al., 2015) and political (Courtwright, 2010) causes of addiction. Sociologists argue that individuals are driven to drugs by social problems such as poverty and inequality (Weinberg, 2011). Anthropologists

compare drug use across cultures and times and write rich accounts of addiction in specific social contexts (Singer, 2012).

4.2 Drugs as tools

While addiction to illicit drugs is a serious social problem that devastates lives, it nonetheless represents only a small fraction of drug use, since most contemporary humans use drugs regularly. Yet the impact of mundane drug use has not received much attention, partly because much of it is not acutely harmful to health. How should we conceptualize mundane drug use, and what is its impact on individuals, societies and culture?

Muller and Schumann (2011) propose a neurobiological framework in which people are seen to instrumentalize drugs, using them as tools to manipulate mental states in order to achieve particular goals. According to this framework, individuals learn the properties of the drugs in their environment, and what can be achieved with them in particular circumstances. Individuals thereby develop a “toolkit” of drugs, which for many will consist of the mainstream, socially-approved drugs of their culture, in particular the “big three” – caffeine, alcohol and nicotine - and commonly-used pharmaceuticals. This framework does not begin by assuming that drug use is a problem, but rather assumes that people use drugs to achieve goals that are important to them. The implication is that researchers should identify the drugs and goals in question, and investigate how people develop the toolkit and achieve goals with it.

The drug instrumentalization framework is based on several pieces of empirical and theoretical work. The possibility that drug use has an adaptive benefit (enhances survival and reproduction) has been proposed by Lende and Smith (2002) who suggested that drug reward acts as a substitute when natural reward cannot be achieved, by Lende et al. (2007) who found that people used illicit amphetamines primarily to enhance productivity, and by Hagen et al. (2013) who demonstrated that some drug use represents a defence against parasites (see also Roulette et al., 2014). Other research has reported users seeking benefits related to mental health, stress reduction, cognitive function, productivity and sociability (references in Muller and Schumann, 2011, p. 295). On this basis it is likely that people are able to detect the affordances of particular drugs and make rational decisions to use them when it would benefit. This implies a cost-benefit calculation which may take into consideration financial, health, legal and social factors. Muller and Schumann propose that a principal problem that drugs solve is the need to rapidly adjust to micro-environments, such as workplaces and social settings, in which individuals are under pressure to hold a particular mindset regardless of their current circumstances. Being able to control one’s emotions, cognitive functioning and fatigue level can be essential to success in many social settings. Thus individuals learn to use caffeine, alcohol, nicotine and/or other drugs to attain the state of mind required in a given situation. Psychiatric medicines and cognitive and physiological enhancers fit easily in this framework.

Instrumentalized use of drugs can impact culture in several ways. In competitive social settings such as workplaces, sporting fields and nightclubs, we should expect that the steadily-increasing availability and variety of drugs would over time create a competitive “arms race” of increasing behavioural adaptations: such as ever-increasing focus and productivity at work, euphoria and sociability at social gatherings, and enhancement of physical and mental abilities. Competition would motivate people to push the boundary between instrumental and harmful use, with some crossing into addiction, and this would lead to regulatory attention being focused on particularly addictive drugs and on those believed to proffer an unfair advantage. Competition would create a constant demand for new, improved drugs to meet life challenges. Drug use would become steadily more universal and globalized as more people felt they must

adopt these tools. Evidence for this view can be seen in the historical record, in which new drugs are constantly discovered and invented and spread through commerce and colonization.

Other research supports the drug instrumentalization framework. Oldani et al. (2014) describe drugs as a set of tools for modifying or enhancing mood, emotional states, behaviour and social relations. Studies of the use of prescription stimulants such as Adderall (e.g. Petersen et al., 2015) show that students take drugs in order to achieve better grades and enjoy academic work. Farah et al. (2004) noted that alteration of brain function can be used to enhance normal individuals as well as to treat mental dysfunction in those who are ill. Glannon (2006) noted that some medicines erase unhelpful memories and enhance useful ones. Wiegel (2015) found that teachers use drugs for cognitive enhancement and reduction of work-related stress. Kirmayer and Raikhel (2009) in a special issue of *Transcultural Psychiatry* showed how psychoactive medications are increasingly used to enhance performance, personality and self-presentation, emphasizing that this is a contemporary manifestation of a long (pre)historical trend to seek transformation through drugs.

4.3 Pro-sociality and moral behaviour

It would be a rare social gathering that did not involve the consumption of caffeine, alcohol, tobacco, comfort foods or other psychoactive substances; the choice depending on culture and context (Sherratt, 1995a; Hayden, 2014). Anthropologists have described the apparently universal centrality of drug use in social life. In the collections edited by Goodman et al. (1995) and Withington and McShane (2014), Hugh-Jones, Von Gernet, Hirsch and Lovejoy (all 1995) detail the key social roles of drugs in the Amazon, pre-colonial North America, Papua New Guinea and Sudan respectively, while Richards, Osborne, Nugent and Hsu (all 2014) demonstrate similar roles in renaissance England, ancient Greece, contemporary Africa, and colonial Taiwan. Heath (1958) found that consuming high doses of alcohol, to the point of unconsciousness, contributed to Camba social solidarity and created bonds even between introverted people (discussed by Singer, 2012). Joe-Laidler et al. (2014) found that ecstasy helped clubbers “open up, trust others, and achieve emotional connections that are difficult or impossible otherwise”. Stromberg (2012), studying smoking among college students, argued that drugs interact with the loss of agency experienced in social gatherings to create a Durkheimian “collective effervescence”.

It is likely that the association between socializing and drugs is built upon their pharmacological properties. Many drugs influence an individual's perceptions of and interactions with other people. Pro-social behaviour is facilitated through mechanisms such as reduction of anxiety, enhancement of self-confidence, suppression of fatigue, and disinhibition of communication (Muller and Schumann, 2011:298). Nicotine (Todd, 2004), alcohol (Cooper et al., 2002), and other drugs (Sinha, 2001) reduce social stress, while alcohol enhances mood and reduces symptoms of depression (Muller and Schumann, 2011). Empathogens such as ecstasy increase sociability and make identification of social threat less accurate (Bedi et al., 2010). Stimulants improve theory of mind and empathy in children with ADHD (Maoz et al. 2014). Enjoyment of social interaction is enhanced by exogenous opioids (Trezza et al., 2011), while alcohol is used to remedy an inability to interact socially (Martinotti et al., 2009). Withington (2014) argued that drugs make “loss of cognitive and bodily control” ubiquitous in socializing.

An important aspect of drug-modulated sociality is the ability for some drugs to reduce the subjective stress of living in groups (Velea and Hautefeuille, 2007). People and animals suffer crowding stress (Armario et al., 2008; Brown and Grunberg, 1995; Calhoun, 1973; Epstein, 1981) which is mediated by serotonin (Daniels et al. 2000) and relieved by a range of

drugs including anti-depressants (e.g., Naitoh et al., 1992), alcohol (Nagaraja and Jeganathan, 2003), opiates (Xigeng et al., 2004) and high-caloric food (Coccurello et al., 2009). In rats, crowded conditions lead to intense competition to establish a status hierarchy, and to anxiety and depression in individuals who suffer social defeat (Leedy et al., 2015). A marked feature of the human story has been population growth and an increase in the proportion of people who live in cities (United Nations, 2012). Ancient and novel drugs may have supported this trend by enhancing prosocial behaviour and alleviating crowding stress (Wadley and Hayden, 2015).

Not only recreational but prescription drugs can increase prosociality. Humans are a social species and have evolved proclivities to behave in ways that benefit others: these are governed by psychological mechanisms that help ensure that the benefit-giver (or their kin) is not disadvantaged (Kurzban et al., 2015). These psychological mechanisms of ethical judgement can be pharmacologically manipulated. Antidepressants that target serotonin receptors reduce hostility and increase warmth and gregariousness (Ilieva, 2015). Pieters and Snelders (2009) argue that the line between healing mental illness and enhancing the normal mind is fine and frequently crossed, with consumers taking pharmaceuticals to “make them feel better about living in a modern world.” A number of existing, commonly-prescribed pharmaceuticals modify moral judgements and behaviour, in particular propranolol and drugs that target serotonin or oxytocin (Levy et al., 2014). Users of these drugs are more likely to forget traumatic events, are less risk-averse, more cooperative and less critical, will distribute money more fairly, and are easier to exploit and more trusting (even after betrayal), though only to in-group members. People’s willingness to harm others can be manipulated by administration of serotonin reuptake inhibitors and dopaminergs (Crockett et al., 2015). Levy et al. point out that for drugs that are used widely, even small ethical reorientations in individuals can aggregate to have a significant impact on how a large group functions. Ethicists are debating whether “moral enhancement” through drugs ought to be implemented, since while society might benefit from reduced immoral behaviour and increased public safety, this occurs at the expense of the individual whose morality is corrected (Focquaert and Schermer, 2015).

4.4 Mediation of hierarchy and status

Status hierarchies feature in many species. Among humans they are especially prominent in post-Neolithic groups, with most contemporary humans living in highly complex societies (Richerson and Boyd, 1999) that feature great economic inequality (Saez and Zueaman, 2014). Drug use can influence and be influenced by status hierarchy, and drugs can mediate political and economic relationships, while both signalling high status and providing solace for those without it.

Drugs are highly prized, and if access is controlled or supply is limited, can confer status on the user and power upon the gatekeeper. Ritual use of entheogens among foragers was restricted to a religious elite, whereas farming societies are characterized by widespread use of drugs with more complex political influences. In complex foraging groups, aspiring “big men” have used drugs as components of competitive feasting, designed to lure potential allies and followers into relationships of debt and political favour (Hayden, 2014). Drugs have been used to compensate and control workers in large-scale societies such as the Incan (Staller, 2009; Morris, 1979), Aztec (Mitchell, 2004), Egyptian, Sumerian and other Near Eastern states (Jennings et al., 2005). Drug were used by European colonizers to induce natives to engage in labour, and then to increase their work efficiency, intensity, and duration (Jankowiak and Bradburd, 1996). Courtwright (2001, p.135) wrote that: “next to profits and taxes, the utility of drugs to acquiring, pacifying and fleecing workers proved to be their greatest advantage to elites”.

Drugs can operate to increase an individual's tolerance of holding low status. They are particularly attractive to those whose status gives them fewer opportunities to receive natural rewards (Nesse, 2002). Social defeat precipitates use of drugs by animals (Bardo et al., 2013, pp. 276-280), including cocaine (Haney et al., 1995) and alcohol (Hilakivi-Clarke and Lister, 1992, Wolffgramm and Heyne, 1991). Comfort foods are used by workers to address effort-reward imbalance (Kouvonen et al., 2005) that arises when physical or mental effort is not commensurate with pay and status (Siegrist, 1996). Cameron and Jones (1985) suggest that drugs of solace contribute to maintaining working class compliance. The idea that political hierarchies are facilitated by drug use has been explored also in fiction. Aldous Huxley in *Brave New World* imagined a society in which ordinary citizens are content with their social roles due to the action of government-supplied "soma" (discussed by Smail, 2007). In *Futurological Congress*, Stanislaw Lem describes an overpopulated future in which drugs can produce any desired emotion and are added to the water supply to subdue the masses (discussed by Oldani et al., 2014).

Withington (2014) notes the multiple ways in which the "close relationship between intoxication and power" plays out in cultural and political life, with drug use acting as "the lubricant of political patronage; the pledge of ideological loyalty; the rites of manhood; the embodiment of taste, civility, privilege, subordination, and exclusion". He noted that while drugs may console the lowly-ranked, use is certainly not restricted to this stratum but is enjoyed "at all levels of the social hierarchy". It is control of the production and distribution of drugs that confers political power, and this is visible in emergent social complexity (Hayden 2014) and in the contemporary ghetto (Karandinos et al., 2014). Authors in Withington and McShane's (2014) collection provide multiple examples: Shortall (2014) describes counterculture leaders who controlled the supply, method, and meaning of drug use; Sennefelt (2014) describes the role of alcohol gifts in the workings of 18th century Swedish politics, a system which "created a man who knew his place in society and performed his role correctly in relation to other men and in relation to patriarchal norms"; Nugent (2014) describes feasting systems in Africa in which "the ability to supply substantial quantities of beer for collective consumption made a clear statement about the location of power and wealth"; Earle (2014) notes that Incan rulers provided beer in return for the right to assemble communal labour; McShane (2014) describes the necessity of regularly and publicly drinking an oath to prove one's loyalty in 17th century England, noting that even today "the refusal to drink alcohol in company can still elicit a suspicious response".

4.5 Willingness to work and to accept delayed rewards

Regular, arduous work for non-immediate payoff is a ubiquitous feature of human life and involves arrangements as varied as farm labour, domestic servitude, factory work and the modern office. Much of what we value in human culture is the result of work; yet most work is aversive to some degree and carries a cost which is perceived subjectively in the form of fatigue or boredom. It is likely that these sensations have evolved to warn individuals of the *opportunity cost* of work, especially regular, repetitive work (Kurzban et al., 2013). That is to say, fatigue is the result of a cost-benefit calculation which signals to the individual that an alternative expenditure of effort might benefit them more. Fatigue makes it difficult to sustain repetitive effort over long periods of time; yet most people at most times and places, particularly if they hold low rank, have needed to work despite feeling fatigued.

Related to fatigue is impulsivity: both are psychological phenomena that modulate willingness to undertake prolonged effort. Understood as an inclination to value immediate reward and to discount future reward (Green and Myerson, 2004), impulsivity is typically viewed by addiction researchers as both cause and consequence of drug-taking (Stein and

Madden, 2012; Kirby et al., 1999). But future-discounting and drug use interact in a complex fashion. While long-term addicts may be impulsive (Bickel and Marsh, 2001), drugs can also enable individuals to *delay* gratification. For example MDMA increases self-control by inducing a feeling of power over delivery of reward (Soubrie, 1986). Opioid users who are currently sated discount the future less than do those who are deprived (Giordano et al., 2002). Individuals who have recently consumed sucrose-laden drinks are more likely to accept delayed rewards (Wang and Dvorak, 2010). Stimulants allow children with ADHD to delay gratification and thereby concentrate on tasks (Reebye and Elbe, 2009).

Drugs have been used throughout human history to motivate workers, to overcome physical and mental fatigue, to inhibit work-related stress, to adapt to work environments and to enhance work performance (Courtwright, 2009; Dube et al., 2005; Grunberg et al., 1999; Jankowiak and Bradburd, 1996; Muller and Schumann, 2011). Organizers in a range of early states provided alcohol, coca and other drugs to workers (Earle, 2014; Staller, 2009; Morris, 1979; Mitchell, 2004; Jennings et al., 2005). Tobacco and coca are used in the contemporary Amazon as a relief or reward after work (Hugh-Jones, 1995). Betel nut is chewed to enhance work in Papua New Guinea (Hirsch, 1995). Kola was provided to work parties of young men in 19th century Sudan to compensate them and combat fatigue (Lovejoy, 1995). Cannabis was smoked by 19th century Indian labourers to obtain relief from work (Mills, 1995). Cocaine and whiskey were given to farm labourers in the 19th century southern United States (Courtwright, 1995). Khat is chewed in the horn of Africa to support work routines, with administration at breakfast and lunch (for energy) and at the end of the working day (for relief) (Klein and Beckerleg, 1995). Kratom is used in South-East Asia to enhance mood during monotonous work (Hassan et al., 2013). Sorghum beer was provided to mine workers in colonial Africa (Nugent, 2014). Alcohol has been provided to personnel in armies and navies since ancient times and formed an important part of military culture, joined later by tobacco and other drugs such as amphetamines, which motivate military personnel by reducing fear and pain during combat and alleviating boredom at other times (Courtwright 2001, p. 140). Drugs and alcohol have traditionally been used to motivate and provide relief to those who perform unpalatable tasks: Courtwright (2001, p.145) lists execution of prisoners, handling of dead bodies, and prostitution as examples. Contemporary university students use stimulants to banish fatigue and make study enjoyable (Petersen, 2015). Prescription drugs are abused by teachers experiencing work-related stress (Wiegel et al., 2015). Comfort foods allow employees to tolerate effort-reward imbalance (Kouvonen et al., 2005). Office workers use caffeine to maintain focus, and then alcohol to adapt to post-work social settings (Muller and Schumann, 2011). Indeed Muller and Schumann (2011) consider high workloads to be a major driver of contemporary drug use.

4.6 Conditioned salience of cultural phenomena

Drugs act upon psychological mechanisms of salience and attention; thus they come to be perceived as important, as do settings associated with drug use (Lende and Smith, 2002). People, places, practices and paraphernalia that have been paired with drug use become attractive and stimulate desire for the drug. Cravings can be triggered by a neighbourhood, a building, a drug-using friend, drug equipment, simulated drug preparation, photos of people using drugs, or money (Childress et al., 1993). Furthermore, social and drug rewards interact to create a preference for social settings in which drug use has taken place (Thiel et al., 2008).

The conditioned place preference is used to study the rewarding properties of drugs and other stimuli in animal models (Huston et al., 2013; Prus et al., 2009). In experiments humans also prefer rooms in which they have had enjoyable drug experiences, avoid rooms in which they have had aversive experiences, and show no preference where drug experiences were inconsistent (Childs and deWit, 2010). Conditioned place preference is a form of classical

conditioning in which a neutral stimulus paired with a rewarding drug becomes attractive in itself (Huston et al., 2013). It is likely partly due to conditioning that drugs “have been fundamental to the nature of sociality and an active element in the construction of religious experience, gender categories and the rituals of social life” (Sherratt, 1995a). Lende (2012) describes ethnographic work that uncovered the roles of salience and habit in the lives of young drug-users in Columbia. Since drug use is associated with many cultural phenomena, particularly those with a social, religious or work element, these settings and activities should be expected to become correspondingly more compelling and engaging.

It should be no surprise then that drug use is intertwined with art and religion. Withington (2014) discusses the connection between art and drugs, discussing two paths of influence: the first being a role in cultural production, the second a role as objects of discussion and representation. Archaeological and anthropological studies provide ample evidence. Osborne (2014) provides an account of the prominence of drinking scenes in ancient Greek art. Withington describes a conflation of creativity and intoxication dating from Islamic poets and Gaelic bards, via the taverns, salons and cafes of Europe to contemporary rock music; at the same time, cultural forms as varied as “printed sermons, tabloid newspapers, political economies, Hollywood movies, Renaissance portraiture, or blogs” have provided a forum for public discussion and representation of the materials, practices, policies, economics and morality of drug use.

Archaeologists can trace the connection between art and drugs back further. VanPool (2009) describes representational practices in shamanist proto-religions around the world and in pre-history. Alongside hallucinogens, shamans use drumming and chanting to achieve altered states of consciousness. Drug-induced experiences such as visual and auditory hallucinations, the sensation of flying and of dying, are portrayed in ancient rock art, paintings and pottery. Visual hallucinations in particular, often consisting of regular geometric patterns of dots, grids or spirals, are a feature of much of the art of forager groups. Extreme nicotine intoxication blocks colour receptors so that users only see white, black and yellow, while peyote boosts perception of certain vivid colours; these influences are visible in ancient art, clothing and pottery. Denizens of the spirit world with which shamans commune are also often depicted. VanPool (2009) discusses the evidence for this in America; similar arguments regarding prehistoric European art are reviewed by Guerra-Doca (2015, p. 771). The places in which shamans take drugs, including caves and buildings, assume cultural importance (see VanPool for references and discussion). Global evidence suggests an early association between drugs, religion and art. Subsequent developments into contemporary times provide numerous examples of the influence of drugs upon cultural production.

The presence of drugs and representations thereof in grave goods and tombs also indicates that drugs played significant roles in early religions. Zapata (2004) describes images of poppy capsules in Bronze Age European art and personal ornamentation. Guerra-Doce (2015) describes artistic depictions of psychoactive plants in ancient Mesopotamian, Egyptian, Greek and Etruscan sites. Clarke and Merlin (2013) propose that cannabis influenced the world view and ideology of early humans, precipitating the invention of invisible spirits and becoming a means by which people could communicate with their gods. Chocolate was used in Mayan rituals and beer in Incan religion (Morris, 1979). Drugs continue to serve as sacraments and components of rituals. Alcohol plays a role in Jewish and Christian ceremonies and Chinese ancestor worship (Sherratt, 1995b). Drugs are also regulated by religion (Kirmayer and Raikhel, 2009) and some are banned, though sometimes inconsistently (Matthee, 2014).

The synthesis of new hallucinogens in the mid-20th century, contemporaneous with a rekindling of interest in ancient mystical uses of psilocybin, renewed interest in the links between drugs and spirituality (Shortall, 2014). While LSD was banned in the 1960s, youth

interest in drug-enhanced spirituality resurfaced in the rave scene of the 1980s and 90s (Joe-Laidler et al., 2014). For many young people, large communal dance parties fuelled by empathogens, hallucinogens, stimulants and disassociatives, sometimes drawing on traditional mystical practices or held in remote sites, represent a new kind of religion (chapters in St John, 2004).

4.7 Inspiration for trade and colonialism

Drugs have comprised a significant proportion of commercial trade since ancient times. Van der Geest et al. (1996) argues this is due to a combination of high desirability and convenient physical properties; “their ‘thinginess’ provides patients and healers with a means to deal with the problem at hand” (p. 154). The potency of drugs relative to their bulk, and their suitability to being packaged and transported, have made drugs powerfully attractive to commercial interests.

David Courtwright in *Forces of Habit* (2001) provides a detailed account of the expansion of drug commerce from the European discovery of America and development of Atlantic trade networks to the present. He describes a “psychoactive revolution” in which people acquired “more, and more potent, ways of altering their ordinary waking consciousness” (p. 2). The New World drugs brought to Europe were seen initially as exotic medicines but over time became more widely adopted, first for self-medication and then for recreational use. (This pattern has repeated for modern drugs such as heroin and amphetamines.) In the New World, drugs were used to barter with indigenous groups for prized commodities such as furs. Distilled spirits and tobacco were perfect currencies (for the colonists): highly prized by indigenous Americans, their psychoactive effects caused natives to barter less wisely, and addiction played a significant role in the decline of indigenous opposition. Commodities such as tobacco and sugar (much of which was turned into rum) were major components of European and colonial economies, being non-durable goods that enjoyed insatiable demand, leading to ever-expanding trade, infrastructure and workforces (p. 147). Courtwright lists colonialism, trans-Atlantic slavery, industrialization and the building of railroads among the ways in which the drug trade shaped the modern world (2001, p.167).

In the 19th and 20th centuries, vendors of “big three” drugs began to employ advertising to differentiate themselves from competitors, to stimulate demand and to train new users. Mechanized manufacturing and better transport led to the appearance of global markets and a globalized culture emanating from America (Courtwright, 2001, ch. 6). Courtwright, Lovejoy (1995), and Smail (2007) emphasize the social impact of New World drugs upon Europe, with Smail quoting August Ludwig Schlözer (d. 1809) that: “the discovery of spirits, the arrival of tobacco, sugar, coffee and tea in Europe have brought about revolutions just as great as, if not greater than, the defeat of the Invincible Armada, the wars of the Spanish Succession, the Paris Peace, etc”.

Psychopharmaceuticals still comprise a significant proportion of world trade, operating at “the highly profitable nexus of science, marketing and human desire” (Oldani, 2014). The use of antidepressants has burgeoned (Elliot and Chambers, 2004), with 11% of Americans aged 12 and over using selective serotonin reuptake inhibitors (SSRIs) in 2008 (Pratt et al., 2011), and 6% of American children taking amphetamines such as Adderall to treat ADHD (Visser et al., 2014). Antidepressants are so widely used that it has been proposed that these drugs influence money market trading (Nesse, 2000) and the behaviour of fish after they enter waterways (Guler and Ford, 2010). Following pioneering work by Van der Geest et al. (1996), anthropologists have examined the proliferation of psychopharmaceuticals and its influence upon cultures. A collection edited by Jenkins (2010) asks how cultures are transformed when much of the

population regularly ingests psychoactive medicines. A special issue of *Culture, Medicine and Psychiatry* (Oldani and Ecks, 2014) examines their influence on contemporary life, debates around over-prescription and power relationships among drug companies, doctors and patients. Ecks (2014) describes informal “doctors” in rural India who prescribe and dispense antidepressants and are tolerated because they address an enormous treatment gap. Oldani (2014) describes high usage of antidepressants, anxiolytics and antipsychotics in rural and post-industrial areas, and shifting popular understandings of sorrow and anxiety due to drug company campaigns (Oldani, 2014).

5 Drugs and the human story

Much of the anthropological work reviewed to this point comprises detailed accounts of instances of drug use in particular cultures. This final section reviews holistic syntheses of the role of drugs in the larger human story.

In *On Deep History and the Brain* (2007) and *An Essay on Neurohistory* (2010), Daniel Smail draws from the past thousand years of European history to argue that an increasing range and availability of psychotropic drugs enabled the emergence of new kinds of social control based on manipulating psychological states, which Smail calls “teletropy”. He argues that whereas organized state violence is a primitive form of teletropy intended to create stress and submission, the appearance of “movies, gossip TV shows, novels, music, shopping, sports, coffee, alcohol, drugs, sex, pornography” (p. 161) has enabled a form of governance (which Smail calls “autotropy”) in which citizens willingly manipulate their own emotions: “European societies, between the twelfth and the nineteenth centuries, witnessed a tectonic shift away from teletropic mechanisms manipulated by ruling elites toward a new order in which the teletropies of dominance were replaced by the growing range of autotropic mechanisms available on an increasingly unregulated market” (p. 186). If political structures have been shaped by psychotropy, it would appear that mundane, mainstream drug use, and not just addiction, has had important influences on human culture.

The drug instrumentalization framework (Muller and Schumann, 2011) would understand autotropy as a rational response to social pressure to perform acceptable emotions and behaviours. Autotropy is reminiscent also of self-domestication, an idea which several authors propose occurred among humans (Leach 2003). Domestication usually refers to morphological or behavioural change in response to human manipulation of selection pressures. Nesse (2007) proposed that “humans have been domesticated by the preferences and choices of other humans. Individuals who please others get resources and help that increase fitness. Aggressive or selfish individuals get no such benefits and are at risk of exclusion from the group, with dire effects on fitness” (p. 4). Drugs would allow this to occur not just through the slow route of genetic change but in real time, directly changing the social milieu and allowing individuals to adapt to it. Smail notes that the idea that culture devises methods of social control to which we voluntarily succumb is part of an intellectual tradition that includes Karl Marx’s *Das Kapital*, Aldous Huxley’s *Brave New World* (see above), and Neil Postman’s *Amusing Ourselves to Death*. The idea finds early expression in Etienne de la Boétie’s (d. 1563) *Discourse on voluntary servitude*: “theatres, games, plays, spectacles, marvellous beasts, medals, tableaux, and other such drugs were for the people of Antiquity the allurements of serfdom, the price for their freedom, the tools of tyranny”.

Courtwright’s *Forces of Habit* (2001) advances two hypotheses: that drugs played a role in inspiring global trade (reviewed in the previous section), and that they served as colonizers’ tools for subduing native peoples, giving empire-builders the power to attract, pacify and

control labourers at home and in colonies and plantations (p. 135). Courtwright notes that opium-smoking Chinese coolies were believed to be the most reliable labourers in the world, while workers in Egypt, Jamaica, Russia and America were paid in alcohol or drugs or spent most of their wages on these, allowing them to tolerate their work while dooming them to an endless cycle of earning and spending. Courtwright argues that the use of drugs as tools of control does not represent a conspiracy by elites, but arises naturally when workers seek drugs which assuage tedium and pain while simultaneously preventing upward mobility.

Though Smail draws mainly upon the historical record, he notes that technologies for psychotropy appeared much earlier: “The effect of the Neolithic transformation, in this neurohistorical perspective, brought about the conditions necessary for a rapid increase in the range of economic, political, and social devices that serve to modulate the body states of self and others.” This transition, which occurred at several sites in Asia and America from about 10,000 years ago and subsequently spread to much of the world, involved a number of major changes to human lifeways. The adoption of farming saw drug use expand from infrequent use by religious specialists to regular, widespread use of emotion-regulating drugs such as alcohol, coca and tobacco. Significant changes to social structure and behaviour saw small, mobile, egalitarian forager groups transition to sedentary life in large, hierarchical societies. Some authors have asked whether the appearance both of expanded drug use and complex societies could be linked. Archaeologist Brian Hayden has proposed that cultivation was initially adopted, not for subsistence in the face of food shortages but to support competitive feasting, a practice used for building political power in many traditional societies. Feasting is widespread among complex hunter-gatherer, chieftain and state societies, but not among pre-Neolithic foragers. It is used by ambitious aggrandizers to acquire allies and followers through debt and obligation (Dietler, 2001; Hayden, 2014). Important to successful feasting is the provision of highly-prized commodities such as alcohol. Collective drinking strengthens social bonds and makes psychologically salient the people, places and activities that co-occur with drinking. Hayden (1990) argues that competitive feasting drove the spread of cultivation, subsequently leading to institutionalized farming.

Supporting this hypothesis, Hayden et al. (2012) recently demonstrated that the earliest cereal farmers in the Near East and China were probably brewing alcohol. Similarly, early farmers in America cultivated maize for alcohol (Smalley and Blake, 2003) as well as tobacco (Groark, 2010) and coca (Dillehay, et al. 2010). Wadley and Hayden (2015) argue that expanded drug use supported cultural change by: 1) providing a motive to adopt and maintain cultivation; 2) enhancing pro-sociality, allowing the maintenance and governance of larger, more coordinated groups; 3) instilling acquiescence in and providing solace to subordinates; 4) enticing people into labour arrangements, enhancing their efficiency, and compelling them to keep working. This is similar to the mechanisms proposed by Smail and Courtwright, but occurring earlier and at smaller, more localized scales.

As a tool for successfully negotiating life in large groups, drugs became an important component of a human-constructed “niche”, helping subsequent generations adapt to new social environment different to that in which their ancestors evolved (Reid, 2011; Smith, 2011). This niche is due to a manipulation not of the natural environment but the social. The large, relatively stable, coordinated groups that appeared after Neolithization in turn supported further innovation via cumulative technological evolution or “cultural ratcheting” (Tennie et al., 2009). Such groups gained an advantage over rivals because suppression of in-group competition improved the ability to compete with other groups (Alexander, 1987) so that over time farming societies dominated much of the world. As Smail (2007) asserts: “All these changes created, in effect, a new neurophysiological ecosystem, a field of evolutionary adaptation in which the sorts

of customs and habits that generate new neural configurations or alter brain-body states could evolve in unpredictable ways” (p. 155).

In conclusion, drugs have influenced important aspects of culture from social life to religion, politics to trade, for many thousands of years. By loosening the constraints of inherited behavioural proclivities and encouraging engagement in activities that are not tied to optimal fitness payoffs, drugs broaden the range of behaviour performed. Therefore it can be argued that drugs are not merely components of human culture, but enablers of cultural change.
