ABSTRACT

Future directions for spatial information management in Australia, from a land administration perspective, are discussed. Sustainable development, micro-economic reform, globalisation and technology are highlighted as the drivers for change. The changing spatial information environment with emphasis on land administration and cadastral issues is examined by drawing on research being undertaken at the University of Melbourne. Issues concerned with future land administration infrastructures such as the changing humankind to land relationship, cadastral reform and native title are highlighted. Specific cadastral and land administration issues and technologies which impact on spatial information strategies are reviewed, including understanding the business-infrastructure relationship in spatial information management, modelling the maintenance of cadastral systems, the changing nature of spatial data infrastructures, the spatial hierarchy problem, the importance of developing partnerships and the impact of communications and WWW technologies. The paper concludes by emphasising that any government spatial information strategy is intimately linked to land administration and is influenced by global drivers such as sustainable development, micro-economic reform and globalisation, as well as technology. Understanding the inter-dependence between these global drivers is a key to successful spatial information management strategies.

KEYWORDS: Spatial information management, land administration, cadastre, cadastral reform, spatial data infrastructures, GIS, WWW, IT, spatial hierarchy

INTRODUCTION

This paper attempts to explore the future directions for spatial information management in Australia from a land administration perspective. It draws heavily on current spatial data infrastructure (SDI) and cadastral research being undertaken in the Department of Geomatics at the University of Melbourne. It is acknowledged that the views expressed in the paper are influenced by this research and the inevitable biases of the author. If there is one over-riding principal or theme in the paper it is that land administration systems are a key component of the infrastructure that supports and facilitates the way society interacts with land. This is the focus of the research mentioned above. While this research focuses on Australia it is undertaken in a global context.

When planning future strategies for spatial information management, governments worldwide sometimes just concentrate on the technology and do not consider other influences or drivers – they do this at their peril. Importantly land, land issues and land administration are critical components of GIS; but all too often they are forgotten. Too many

administrators and researchers unfortunately just focus on narrow technical and scientific issues. Within the land administration context, it is land which distinguishes GIS from being just the spatial component of information technology (IT).

There is no doubt that we are in the midst of a spatial information revolution as a critical component of the IT revolution. How is this manifesting itself and what is its impact? In simple terms this includes the emergence of new disciplines and professions, the emergence of a new private sector and new institutional structures in government. It is resulting in new research, new scientific and professional journals and new educational programs. But most importantly it is resulting in the availability of on-line spatial data, especially about land and land parcels, which has the potential to significantly change the dynamics of civil society.

Three related perspectives are considered in undertaking research into these developments which generally focus on land administration infrastructures. These perspectives guide the research mentioned above. First is an appreciation of the global drivers for change in the spatial information world. Next is an analysis of the impacts on the design of the land administration systems, and particularly the cadastral component, which underpin much of the spatial information trends and developments. This in turn identifies issues and opportunities in the spatial information tools which support these trends and developments, such as spatial data infrastructures and the Internet. This hierarchy of perspectives is shown in Figure 1. This is expanded in the research framework used for SDI and cadastral research at the University of Melbourne (Figure 2).

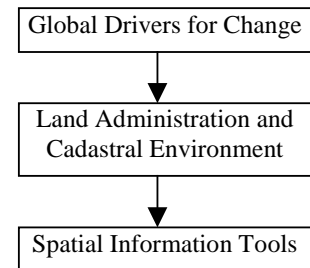

Figure 1. Hierarchy of Perspectives

This research framework attempts to describe the social system in which spatial data infrastructures and cadastral systems develop. In simple terms it recognises that society has certain needs for spatial and land related data, albeit these continually change. The model recognises there are legal, administrative, technological, innovation and diffusion processes and pressures, which influence the inevitable conceptual models which are developed to address the needs of society. The model also recognises that these needs, pressures and resulting models operate on a hierarchy of levels from local to global.

The paper is based around this research model and more specifically the three perspectives of global drivers for change, land administration and cadastral trends, and spatial information tools.

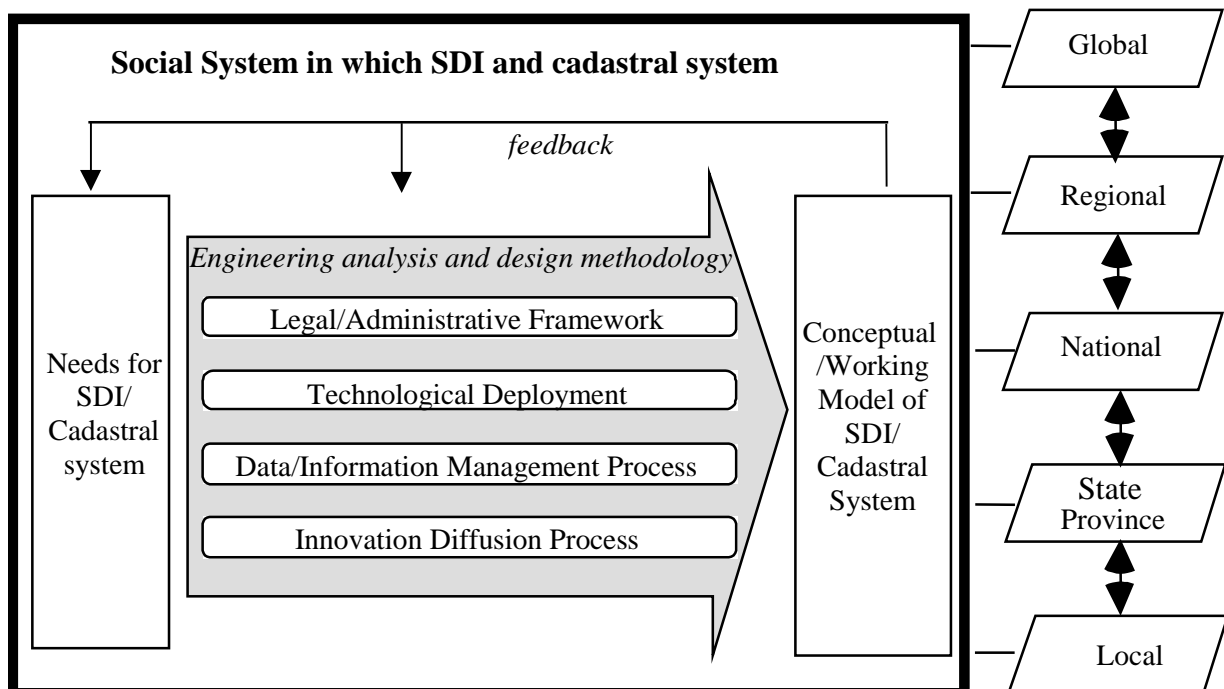

Figure 2. Research framework for Spatial Data Infrastructures and Cadastral Research

THE DRIVERS FOR CHANGE

There is no doubt that technology is a major driving force in changing the face of our spatial information world, but in many discussions and policies you could be forgiven for thinking it was the only driver. In addition to technology, the major drivers of sustainable development, micro-economic reform and globalisation are discussed below.

Sustainable development

Sustainable development will be the driving force in land administration policies developed in the decades ahead. Even though sustainable development has been the catchcry across the globe since the mid-1980s, the implementation of seminal documents such as Agenda 21 arising out of the United Nations (UN) Environment Summit and the Habitat II Global Plan of Action arising out of the UN Cities Summit, has been disappointing.

Sustainable development means development that effectively incorporates economic, social, political, conservation and resource management factors in decision-making for development – in other words being able to do what we want to do in perpetuity. The challenge of balancing these competing tensions in sophisticated decision making requires access to accurate and relevant information in a readily interactive form. In delivering this objective, information technology, spatial data infrastructures, multi-purpose cadastral systems and land information business systems will play a critically important role. Unfortunately modern societies still have a long way to go before they will have these infrastructure and business systems required to support sustainable development. Understanding the land administration requirements and infrastructure to support sustainable development will be one of the major issues facing governments over the next decade.

The last three decades has been an era of growing environmental awareness. Without doubt this has dramatically influenced Australian land administration systems. The 1990s have seen the growth of importance of social issues relating to land. Evidence of this is the fall of apartheid, the fall of communism, indigenous land rights and women's access to land. Both the environmental and social drivers are key components of sustainable development.

Micro-economic reform

Micro-economic reform has had a dramatic impact on the development of spatial information management in Australia. These reforms have impacted on all levels of government and have resulted in the now common activities of downsizing, privatisation, cost recovery, performance contracts, quality assurance, and the list goes on. In the State of Victoria, an important element of the reform had been the restructuring of government departments (based on the Funder-Provider model) to sharpen their focus on core business or service delivery objectives and improve cost efficiency. This is to ensure that management decisions take account of the full costs of service delivery (Williamson *et al.* 1998). Interestingly the funder-provider model is now being increasingly criticised.

Another important component of micro-economic reform has been the National Competition Policy introduced by the Federal Government in 1993. All State governments agreed to implement this policy in 1995. The Victorian State Government also committed itself to the introduction of competitive neutrality principles to both government-owned businesses and predominantly tax-funded government services. The principles of competitive neutrality aim to ensure that government businesses and services do not enjoy any net competitive advantage through immunity from taxes, regulations, debt charges, and in general, full cost attribution (Williamson *et al.* 1998).

The result of all these initiatives has seen a dramatic change in the structure, mandate and operation of the government, private and academic sectors in Australian society. These changes have had a very large impact on the spatial information environment. This impact has accelerated with the increasing recognition by governments at all levels that spatial information, and more specifically appropriate spatial business systems and associated spatial data infrastructures, are essential components of any modern economy. Simply without these structures the vision of a virtual world based on electronic commerce will not be possible.

Globalisation

Within tomorrow's world, political patterns, economies and social systems worldwide are undergoing a process of profound and continuing structural change, often termed globalisation. Globalisation is becoming a reality driven by IT and communication technologies. Globalisation means the process of increasing interconnectedness between societies and jurisdictions from a social, economic and political perspective, such that events in one part of the world have increasing potential to impact on peoples and societies in other parts of the world. A globalised world is one in which political, economic, cultural and social events become more interconnected. In other words, societies are affected more and more extensively and more deeply by events of other societies. However the big challenge of globalisation is for individuals, societies and countries to fully participate in this global revolution.

Globalisation has a social, economic and political dimension. The world seems to be shrinking with people being increasingly aware of the phenomenon. The WWW is the most graphic example of this trend, since it is improving interconnectedness between and within individuals in a way never believed or dreamed possible, even a decade ago. It is a pattern of events that seems to have changed the nature of world politics from what it was just a few years ago. The important point is that the world is changing and the global village is becoming a reality.

Within this era, there is an emerging global policy, with multinational social and political movements and the beginnings of a sharing of allegiance from the state to national, regional and international bodies. Globalisation is a new stage in world policy that will assist in improving the quality of lives of people by thinking, working and cooperating together on common concerns.

There are many factors which encourage people to work together as part of globalisation. These factors include:

- synergy of information, technology and access, which effect each other;
- expanding global interdependence;
- increasing emphasis on sustainability; and
- increasing focus on the individual in areas such as health, personal rights, privacy, quality of life, recreation, etc.

By understanding globalisation and its social, economic and political impact on our society, we are in a much better position to develop appropriate spatial information strategies. One of the most important results is that today, more than ever before, it is important to look beyond our own national boundaries. With this in mind, many countries throughout the world believe that they can benefit from better management of their spatial information by taking a perspective that starts at a local level and proceeds through state, national and regional levels to a global level. This has resulted in the development of the Spatial Data Infrastructure concept with a hierarchical relationship between these different levels.

Technology trends

New technologies have certainly dictated changes in the development of spatial information management systems. For data capture some examples of the new technologies include satellite positioning systems such as the USA Global Positioning System (GPS) and the Russian GLONAS system, digital data capture by cameras using charged coupled devices (CCD) technology, and remote sensing technologies and especially the new high resolution satellite imagery. The data base technologies that affect the storage of very large data sets have had a major impact on the spatial information revolution and especially the impact on managing large spatial databases and data warehousing. The GIS technologies for data management, manipulation, analysis and integration arguably have had the greatest impact on the spatial information environment, although in the future the communication technologies such as the WWW and the Internet are rapidly becoming the focus of attention. These technologies are increasingly being used for viewing, locating and using spatial data. This paper however is not about describing current and future GIS technologies since they are expertly dealt with in many other forums.

THE LAND ADMINISTRATION PERSPECTIVE

The global drivers described above influence the form of land administration infrastructures which support and facilitate the way societies interact with land. These drivers influence the development of the different land administration policies and models adopted by governments, and increasingly by the private sector. These models and concepts can only be developed with a clear understanding of current land administration issues and trends. By its very nature land administration focuses on land tenure and cadastral (land parcel related) issues. The land administration perspective includes understanding the changing humankind to land relationship, cadastral issues such as national cadastral systems in countries which are a federation of states, and land tenure issues such as native title.

The changing humankind-land relationship

One of the most important influences on the development of spatial information management is the changing relationship of humankind to land and the resulting land administration infrastructure required by these changes (Figure 3). To put this in context, it is just over 200 years ago that land markets, as we now know them, developed. This was driven by the industrial revolution and the growth of modern cities. In this environment land changed from being equated to wealth to being a commodity. This then saw the development of land administration systems such as the Torrens System to facilitate land markets. In simple terms the cadastre has evolved in response to these demands from society (Ting *et al.*, 1999).

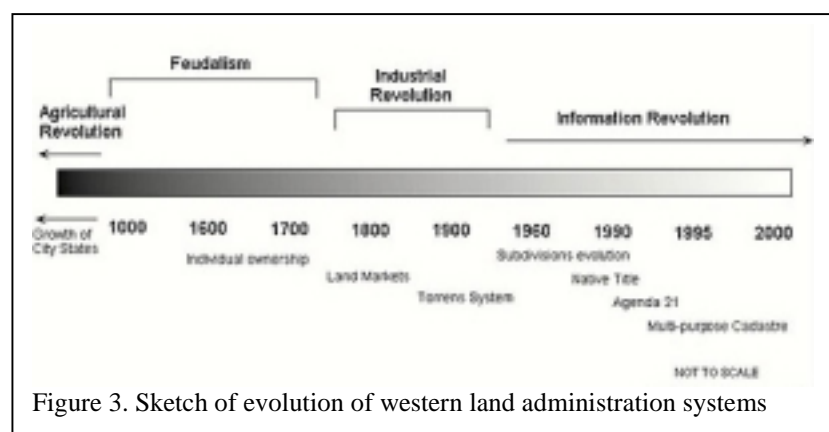

Figure 3. Sketch of evolution of western land administration systems

In simple terms the broad development phases of the changing humankind to land relationship have been:

- Agricultural revolution: land as wealth and cadastre as basic record and fiscal tool
- Industrial revolution: land as commodity and cadastre as a land market tool
- Post-War: land as a scarce resource and cadastre as a planning tool
- 1980s and into the next millenium: land as a scarce community resource and cadastre as a land management tool

These changes in the relationship of humankind to land and the corresponding changes to land administrative infrastructures (Ting and Williamson 1999) as shown diagrammatically in Figure 4.

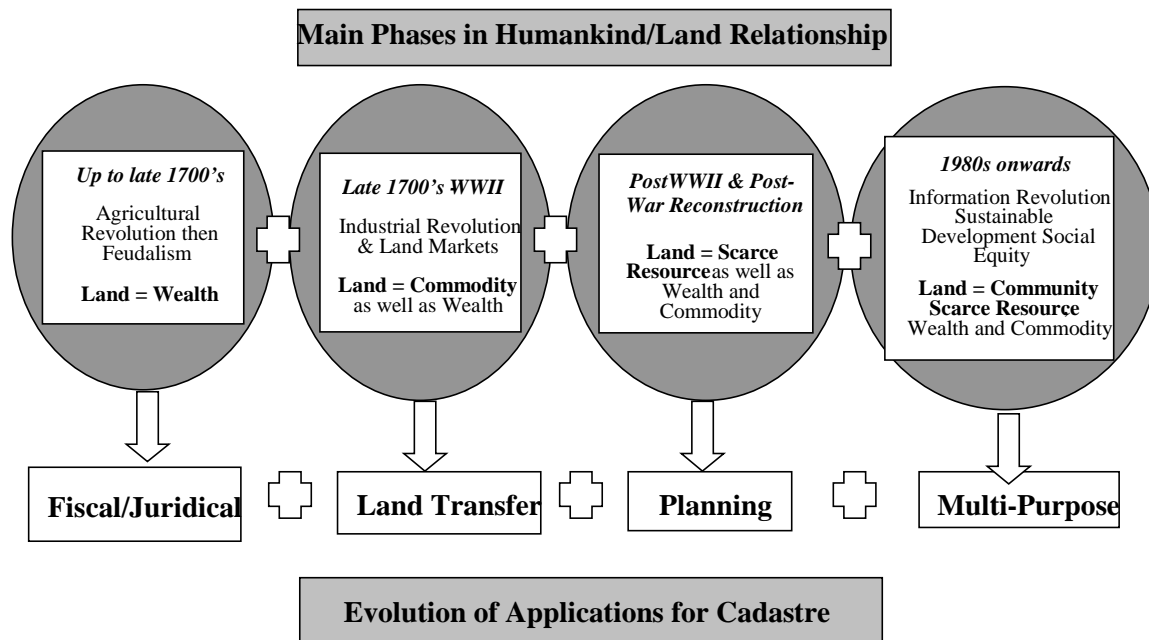

Figure 4. Evolution of the Land Administrative Infrastructure

The lesson from this research is that the relationship of humankind to land is dynamic with the resulting land administrative infrastructures also being dynamic. As a result any government which is attempting to develop future land administration policies and strategies must take this changing relationship into account.

Cadastral reform

Cadastral systems, as a critically important component of land administration systems, are continually evolving as society's attitudes and relationship to land changes. As society's relationship with land becomes more complex in terms of the ever increasing number and form of rights, responsibilities and obligations, our land administration information systems that support decision-making, primarily in support of sustainable development, must also adapt to remain relevant. The resulting cadastral reforms, which have increasingly occurred across all Australian jurisdictions over the last 20 years, give an insight to the issues and trends in both land administration and the supporting spatial information management trends. Following is an overview of some of the issues and trends that has formed the basis of some of the cadastral research over the last decade.

Cadastral systems can no longer rely on manual processes or traditional structures that supported economic or taxation imperatives in the past. Stand alone or isolated approaches that supported individual purposes where data and processes were maintained in separate "data silos", such as land valuation and land titling, are not sustainable. They are being replaced by multipurpose cadastral systems where information about natural resources, planning, land use, land value and land titles, including Western and indigenous interests, can be integrated for a range of business purposes. The design of modern cadastres has seen the application of contemporary system development tools such as case study methodologies and information system concepts and principles. As we move further into the information revolution, a view of what cadastres might look like in a decade or so can give a clearer view of the road ahead.

Commission 7 (Cadastre and Land Management) of the International Federation of Surveyors (FIG) has developed a vision for a future cadastral system called Cadastre 2014 (in the year 2014) (Kaufmann and Steudler 1998). Cadastre 2014 is based on international trends following extensive worldwide research over a four-year period. This document provides the first international benchmark against which cadastres can be measured in terms of development and

reform. A parallel part of the process to develop Cadastre 2014 was an international benchmarking of cadastral systems around the world also undertaken by Commission 7 (Stuedler *et al.*, 1997).

The creation of a digital representation of the spatial cadastre or digital cadastral data bases (DCDBs) has brought not only the benefits of digital information but also challenges in terms of how these layers are maintained and improved in terms of spatial accuracy.

Maturity within the industry allows us to look at decentralised update mechanisms involving a number of the sources, where updates flow across the WWW. DCDBs are moving from graphical accuracy towards survey accuracy related to land use and land value, as user needs in the utility and engineering fields become more demanding. The rapid improvement in accuracy available to users of positional technology, such as with GPS and electronic distance measuring equipment, is also driving the need to upgrade the accuracy of our cadastral databases.

Low cost cadastres are being developed for low value lands such as Australia's semi-arid lands or rangelands. These models are increasingly moving towards multipurpose systems where data is captured by remote sensing technologies. Natural features and improvements such as roads, railways and fence lines can then be used as coordinated occupational boundaries rather than using the traditional fixed boundary approach.

Increasingly cadastres that are complete in terms of coverage and content and kept up to date will be a fundamental requirement for the development of spatial data infrastructures at both the state and national levels. The institutional arrangements for the cadastre as a component of SDI's is also being examined and in particular the role of government as a regulator of cadastral surveying. The role of regulatory boards which have operated on behalf of governments to ensure that competency standards are maintained in this regard where they underpin Torrens title and the state guarantee, is being questioned. Cadastre 2014 and current trends in Australia point towards less government intervention in this area.

Is a national cadastral system possible?

The development of the Public Sector Mapping Agencies (PSMA) national data set based primarily on state and territory DCDBs, together with the commitment to a national competition policy, has raised the concept of national cadastral data sets. However it must be remembered that each state is responsible under the Australian Constitution for land and land matters, which results in each state and territory having slightly different cadastral systems. One of the key differences between the jurisdictions is that different states define parcel boundaries differently. In some states cadastral boundaries can move while in others they cannot. The result is that the concept of a land parcel in the different Australian jurisdictions is different. The major difference is that some jurisdictions permit adverse possession as to part of a parcel and some don't (this means in some jurisdictions a boundary may have moved and is not shown on the DCDB). This difference can also significantly affect the operation of a jurisdiction's land market.

At one level it can be stated that while all the states permit adverse possession and the two territories do not, the differing requirements within each state's own individual scheme must be recognised. For example South Australia only permits adverse possession where land has been abandoned or perhaps informally transferred by the registered proprietor. If a focus is taken on adverse possession of part of a parcel, a situation which can affect the location of the boundary between adjoining parcels, a different conclusion may result. While NSW permits adverse possession it does not allow adverse possession of less than a whole parcel. Victoria on the other hand does (Park *et al.* 1998, Park and Williamson 1999a and 1999b).

A single national cadastre in Australia is technically possible as illustrated by the PSMA mapping base (Mooney and Grant 1997). The positive response from the spatial information industry towards such a product has been very good, suggesting that a single national cadastre is also desirable. However a major possible difficulty is the different approach of each jurisdiction to adverse possession of registered title land, and particularly to part parcel. If Australia decides to adopt common cadastral legislation, it appears that that this "possible difficulty" could prove to be a major stumbling block in moving towards a national system.

Integration of customary and traditional tenures into "western" land administration systems

The inclusion of indigenous interests in land has been recognised by the United Nations in Agenda 21 as important for maintaining and developing a land information system in support of sustainable development. This is a world trend with indigenous interests in land having been recognised and integrated within mainstream land administration systems, such as those in New Zealand, USA, Fiji, Papua New Guinea, and more notably the establishment of the Nunavut Territory in Canada by the Inuit people.

On the one hand the integration of diverse land tenures into a one comprehensive land administration system is essential and inevitable, however it presents many difficulties which have been highlighted around the world. On the other hand

the new spatial information technologies and the emerging multi-purpose cadastral systems offer much potential in assisting in helping solve the inevitable problems in developing the land administration infrastructures that Australian jurisdictions will need over the next 10 years.

Another important cadastral issue results from the High Court's decision concerning Mabo and Wik, and the inception and implementation of the *Native Title Act* 1993. These decisions are driving the integration of two vastly different land tenure systems in Australia, namely traditional Aboriginal land tenure and the Australian Torrens system. The amalgamation must result in future modern multi-purpose cadastral systems in Australia being able to include native title interests while maintaining cultural integrity (Brazenor *et al.* 1999).

UN-FIG Workshop and International Conference on Land Tenure and Cadastral Infrastructures for Sustainable Development

Many of the issues raised in this paper will be the subject of the UN-FIG International Conference on Land Tenure and Cadastral Infrastructures for Sustainable Development to be held in Melbourne from 24-27th October, 1999 (www.sli.unimelb.edu.au/UNConf99/). The conference will launch and discuss the Bathurst Declaration on land administration developed in the preceding week. The Declaration will focus on the reforms necessary to meet the challenges of sustainable development and the changing humankind to land relationship into the future. The Declaration will be the result of a week long residential workshop attended by an invited group of 30 international authorities representing about 20 countries including several UN agencies and the World Bank.

In addition to presenting the Bathurst Declaration on Land Tenure and Cadastral Infrastructures for Sustainable Development, many of the international authorities, and the UN and World Bank representatives will present background papers at the Melbourne conference organised under the following themes:

- Sustainable development as a global trend
- Land – the big picture for change
- Cadastre and land administration: foundations for the future
- Land, information and power
- Water and environmental issues – the imperative to coordinate with land administration
- The Western experience
- The Developing World experience

Professor Don Grant, the NSW Surveyor General and Australian delegate to Commission 7, FIG and the author, as former chairperson of Commission 7 and now Director FIG-UN Liaison for the FIG, are the co-organisers of the workshop and conference. Much of the planning for these events has been undertaken with the assistance from the SDI and cadastral researchers at the University of Melbourne, Land Victoria and the NSW Land Information Centre.

THE CHANGING SPATIAL INFORMATION MANAGEMENT ENVIRONMENT

There are a range of concepts, principles and technologies that have been developed or are evolving to assist in establishing modern cadastral and land administration systems. Following are some of the issues, developments, concepts and trends which have evolved or been highlighted in the spatial information environment in recent times in Australia and have been the subject of research undertaken at the University of Melbourne. They are all characterised by being part of the increasingly rapid change in the spatial information environment and give an insight in current trends and future directions in spatial information management in Australia.

Understanding the business-infrastructure relationship in spatial information management

After studying the uptake and utilisation (diffusion) of GIS in state governments (Chan and Williamson 1996, 1999a), Chan (1998) details and validates a business-infrastructure model that can better describe how and why agencies cooperate to develop a GIS. In this model, a corporate GIS is viewed as comprising inter-related mutual-supporting multi-levelled modules of business process GIS and infrastructure GIS in the context of the business/production activities of the organisation (Figure 5).

Based on this model, a SDI is disaggregated into a collection of modules of hierarchical infrastructure GIS (the shaded ovals). The business process GIS represents the GIS capabilities developed by the *users* (the clear ovals) that rely on the SDI modules to deliver the products and services needed by the

Figure 5. The business-infrastructure model.

geospatial information industry. This GIS may, in turn, nurture the development of new SDI modules, and link different SDI modules together. The inherent relationships between the SDI and the business process GIS in the business-infrastructure model provide a broad framework for spatial information management.

Understanding the complexity of cadastral systems and the maintenance of the spatial component

A cadastral system has two components: textual and spatial. The spatial component consists of cadastral maps, the geodetic framework and survey plans. Maintenance of this spatial component involves updating and upgrading of the proposed, current legal and as built spatial data of land subdivision activities through various means including the Internet (Effenberg, *et al.* 1999, Falzon and Williamson 1998, Phillips, *et al.* 1998, Polley, *et al.* 1997) as illustrated in Figure 6. The goal of the maintenance exercise is to provide a homogeneous statewide coverage of cadastral data with minimum maintenance duplication. As shown in Figure 6, the objective is not just a matter of updating the state DCDB but of providing an updated digital environment for the effective functioning of the cadastral system.

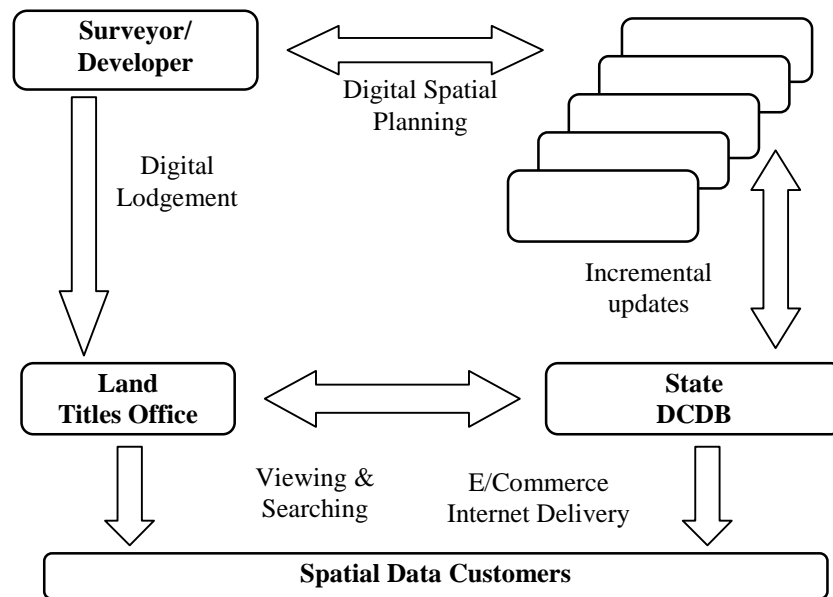

Figure 6. Complexity of a Cadastral System.

The changing nature of spatial data infrastructures

Current spatial data infrastructures (SDIs) are in reality a sophisticated digital version of the systems that most developed nations have had for over 50 years. One important development is the recognition that SDIs comprise people, a clearinghouse/access network, technical standards, an institutional framework and framework data. The spatial data infrastructures of the past were designed and driven primarily by the providers of the infrastructure. An important change over the last decade has been the rapidly expanding numbers of users of spatial data, which are resulting in a proliferation of spatial business systems. These are increasingly influencing and demanding specific characteristics from SDIs. With the rapidly changing spatial information environment and the impact of such technologies as the WWW, GPS, high resolution satellite imagery, communication technologies and sophisticated decision support systems based on GIS technologies, these spatial data infrastructures will inevitably change and develop.

In exploring such changes it is important to recognise that SDIs are increasingly being grouped into a hierarchy (Figure 7) comprising six levels of SDIs, namely, global, regional, national, state (also called provincial), local and corporate (Chan and Williamson 1999b). Ideally with compatible sets of SDIs, users working on issues at a higher level in the hierarchy can draw on data from SDIs in all other levels lower in the hierarchy (Rajabifard, *et al.* 1999).

The spatial hierarchy problem

With the advent of an increasing number of spatial business systems demanding more and more from spatial data infrastructures, problems with the “spatial hierarchy” are increasingly becoming an issue. The spatial hierarchy issue refers to the difficulties in exchanging, aggregating and analysing different data sets based on non-coterminous boundaries (Eagleson, *et al.* 1999).

Figure 8. Current situation of managing spatial data among state agencies

Figure 9. Ideal situation of managing spatial data among state agencies

Figure 8 illustrates the current situation where each agency collects and aggregates data based on their own hierarchically structured boundaries. The bottom layer is the land parcel map. Land parcels are recognised as indivisible units. This is common practice in most countries. As a result, data aggregation is possible within each agency but it results in great difficulties if the aim is to use data from various agencies.

Research is being undertaken to examine trends in such organisations as the Australian Bureau of Statistics (ABS), health and social security departments, and Australia Post to explore the use of Hierarchical Spatial Reasoning (HSR) in assisting in the spatial hierarchy problem. Such an approach has been applied in different applications such as way finding for navigation systems (Car, 1997). The properties inherent in HSR theory make it suitable as the base for a re-organisation of spatial units under a common hierarchy. This research aims to apply the principles of HSR theory to the re-organisation of spatial boundaries. Figure 9 shows a model where all agencies share a common structure that enables cross analysis. By applying HSR to this problem, GIS will hopefully improve its capacity for data integration (one of the items on the agenda of GIS institutions such as the National Center for Geographic Information and Analysis (NCGIA) and the University Consortium for Geographic Information Science (UCGIS)).

Developing partnerships

Partnership refers to the association of two or more people as partners in the carrying on of a business with shared risks and profits. In this context it is generally recognised that no one agency can develop a National SDI (NSDI) with the result that different national SDI coordinating agencies are encouraging NSDI development through partnerships (Federal Geographic Data Committee 1997, AUSLIG 1999). In the USA alone, over 50 major partnership initiatives have been established since 1995 on a thematic, state wide and regional basis. States like Victoria have recently achieved considerable success in developing strong partnerships with local government in providing the State's SDI.

Australia has accumulated significant experience on the development of the cadastral component of its NSDI through a wide range of public-public and public-private partnerships (Mooney and Grant 1997, Williamson *et al.* 1998). Some are successful and some are not, but all are important in understanding how partnerships can be better utilised in cadastral and NSDI development. The issues include standards, cost sharing, privacy, copyright and inter-state/inter-person rivalry. However, the Australian experience also suggests that where there is a need, there is always a solution. It is expected that the determining factors in an on-going research project into partnerships in SDI development will be the type of partnership, the objective, the business driver, organisation settings of the partners and leadership by visionary managers.

Evolving government institutions

The spatial information industry has gone through a major re-engineering over the last 20 years and particularly the last decade. As a result of micro-economic reform, government has increasingly moved away from service delivery to directing and setting policy in the spatial information environment. This has resulted in the growth of a spatial information industry. In the past this industry was considered no more than a cottage industry but through these policies an increasing number of relatively large private sector companies are evolving. Such companies are now able to invest in research and development and can begin to have an export focus.

At the same time as governments recognise the importance of spatial information to economic development and environmental management (sustainable development), government institutions have continued to evolve. A major trend has been the amalgamation of all the land related information organisations into one department, group or unit. A good example is Land Victoria in the Government of Victoria.

There has also been an important increase in spatial information development at a national level in Australia. In the past the only organisation with the ability to provide national spatial data was the Federal Government. However as a result of its mandate the Federal Government focussed on small-scale data. With the growth of medium and large-scale digital data at a state and territory level in Australia, usually based on the cadastre, users have increasingly demanded access to this data as an aggregated product at a national level. This has seen the growth of the Public Sector Mapping Agencies, an excellent example of the partnership concept in Australia, to provide these products.

Another outcome of these changing institutions has been an increasing partnership between academic institutions and both government and the private sectors. With universities also having been dramatically affected by micro-economic reform policies resulting in reduced government funding, universities are increasingly providing the research and development to government, research which was previously provided in-house. This is resulting in some spatial information departments in universities relying on external funds for over 50% of their operating budget.

Impact of the WWW and communications technologies

The WWW and communication technologies are having a dramatic impact on the evolving spatial information marketplace. The use of GIS in land administration over the years, in both the natural resources and parcel based areas, has resulted in the proliferation of many large distributed spatial databases. Such spatial databases require very efficient means of data management and access tools that intelligently guide users to the data. Metadata (data about data) and metadata engines are examples of intelligent spatial access tools, areas where there is considerable research being undertaken. Metadata provides users with information about the data prior to retrieving and using the data. A Metadata engine can use the metadata for searching and retrieving datasets from across the WWW (Phillips et al, 1998). The WWW is also often viewed as storage banks where spatial information can be stored and retrieved locally by Internet users. A prototype developed by Polley uses Java and the Computer Gateway Interface (CGI) language to facilitate a two-way flow of spatial data through the WWW (Polley, 1999).

Increasingly the WWW is seen as an alternative to delivering cadastral information by public bodies to the public. In fact some government organisations are seeing their whole delivery strategy based on the WWW. WWW servers and the emergence of Map Servers also facilitate the move towards the realisation of the multi-purpose cadastre concept described over 20 years ago and more recently in the Bogor Declaration on Cadastral Reform (UN/FIG 1996) and Cadastre 2014. However it is only now, due to the technology, that the vision is becoming a reality. Together with distributed databases, the WWW and Map Servers, a multi-purpose cadastre is expected to allow government agencies to overlay cadastral maps, title registers, planning and other vital land resources live and interactively in order to show the complete legal situation of the land to Internet users across the world. In other words it is becoming increasingly possible to identify all rights, restrictions and responsibilities relating to land over the WWW. No doubt the WWW, together with advanced communication and information technologies, will continue to be one of the major drivers for the future development of spatial information management in Australia.

Education and Professional structures

The spatial information revolution has had many influences on education and professional structures for over 20 years in Australia. One very obvious result has been the establishment and growth of AURISA. However the growth of spatial information has also dramatically affected traditional professional structures and educational programs. Professions such as surveying are being re-engineered and re-invented to accommodate the spatial information revolution, while endeavoring to maintain traditional services. The geography discipline internationally has been a leader in the development of spatial information science although for a range of reasons the Australian geography discipline has not embraced GIS to the same extent.

At the university level the impact on surveying has been very significant. The surveying discipline has been transformed over the last decade. We have seen the adoption in Australia and internationally of the geomatics concept where the focus of the discipline is to design, build and manage the spatial dimension of the natural and built environment. In some universities there has been an increasing alignment with the IT and engineering disciplines, with the geomatics programs at the University of New South Wales and University of Melbourne both being accredited engineering degrees.

At a professional level there has been ongoing discussions for an amalgamation of the spatial professions into one spatial information body. Some accommodation in this regard is inevitable and is only being held back by conservative elements. Unfortunately the clock is ticking for these conservative elements and unless they move to be part of the spatial information revolution they will become increasingly marginalised.

Another important development is the creation of a National Spatial Accreditation Authority jointly between the spatial information industry and professional bodies, being coordinated by The Institution of Surveyors, Australia Inc. Such a move is essential in an increasingly de-regulated environment where traditional bodies like state and territory Boards of Surveyors come under threat as a result of the national competition policy. At the same time as these developments are occurring, related research is being undertaken in the whole question of the statutory control of spatial data.

CONCLUSION

In attempting to overview future directions for spatial information management in Australia from a land administration perspective, examples have been drawn from the SDI and cadastral research. These examples have tried to highlight the complexity and inter-dependency of issues in the area of spatial information management and their multi-disciplinary nature. Most importantly they have endeavored to show that any spatial information strategy at any level of government is an important component of that jurisdiction's wider land administration strategy. In the Australian states and territories, spatial information management is strongly influenced by land administration which is responsive to global drivers. As such any spatial information management strategy must take into account sustainable development, micro-economic reform and globalisation trends and issues, in addition to the obvious technology issues, as they affect land administration.

A key requirement in developing appropriate spatial information management strategies is understanding the relationship between the changing humankind-land relationship, sustainable development strategies, land administration systems, spatial business systems and spatial data infrastructures, while recognising the impact of technology across all these dimensions (Figure 10). In addressing this need, spatial data infrastructures will evolve to accommodate the business needs of sophisticated decision support systems and complex multi-purpose cadastres. The increasing emphasis on business needs as distinct from infrastructure needs of spatial information will inevitably see a re-engineering of current SDIs.

Sustainable development will be the focus for the changing humankind to land relationship into the next millennium. This demands sophisticated land administration infrastructures for the necessary decision-making. These in turn require support from the more generic information technologies integrated with spatial information technologies that can process and package data that is of sufficient quality, accuracy, relevance and interoperability to the decision-maker. Herein lie the many challenges that need to be tackled in developing the next generation of spatial information systems.

BIOGRAPHICAL SKETCH

Professor Ian Williamson PhD (NSW), DrHC (Olsztyn), FTSE, FISAust, FIEAust, HonFMSIAust, LS, CPEng is Professor of Surveying and Land Information and Head of the Department of Geomatics at the University of Melbourne. He teaches and undertakes research in the areas of cadastral, land and geographic information systems, land administration and spatial data infrastructures, in conjunction with his research team. He has undertaken consultancies worldwide in his area of expertise including for AusAID, the United Nations and the World Bank. He was Chairperson of Commission 7 (Cadastral and Land Management) of the International Federation of Surveyors 1994-98, and is currently Director, FIG/UN Liaison 1999-2002. At Melbourne he has been President of the Academic Board and Pro-Vice-Chancellor. He is currently Chairperson of the Victorian Government's Geospatial Information Reference Group. Professor Williamson was awarded the AURISA Eminent Individual Award in 1996.
