ABSTRACT

Background
Depressive disorders are common in young people and are associated with significant negative impacts. Newer generation antidepressants, particularly selective serotonin reuptake inhibitors (SSRIs), are often used, however evidence of their effectiveness in children and adolescents is not clear. Furthermore, there have been warnings against their use in this population due to concerns about increased risk of suicidal ideation and behaviour.

Objectives
To determine the efficacy and adverse outcomes, including definitive suicidal behaviour and suicidal ideation, of newer generation antidepressants compared with placebo in the treatment of depressive disorders in children and adolescents.

Search methods
For this update of the review, we searched the Cochrane Depression, Anxiety and Neurosis Review Group’s Specialised Register (CCDANCTR) to October 2011. The CCDANCTR includes relevant randomised controlled trials from the following bibliographic databases: CENTRAL (the Cochrane Central Register of Controlled Trials) (all years), EMBASE (1974 -), MEDLINE (1950 -) and PsycINFO (1967 -). We searched clinical trial registries and pharmaceutical company websites. We checked reference lists of included trials and other reviews, and sent letters to key researchers and the pharmaceutical companies of included trials from January to August 2011.

Selection criteria
Published and unpublished randomised controlled trials (RCTs), cross-over trials and cluster trials comparing a newer generation antidepressant with a placebo in children and adolescents aged 6 to 18 years old and diagnosed with a depressive disorder were eligible for inclusion. In this update, we amended the selection criteria to include newer generation antidepressants rather than SSRIs only.
Data collection and analysis

Two or three review authors selected the trials, assessed their quality, and extracted trial and outcome data. We used a random-effects meta-analysis. We used risk ratio (RR) to summarise dichotomous outcomes and mean difference (MD) to summarise continuous measures.

Main results

Nineteen trials of a range of newer antidepressants compared with placebo, containing 3335 participants, were included. The trials excluded young people at high risk of suicide and many co-morbid conditions and the participants are likely to be less unwell than those seen in clinical practice. We judged none of these trials to be at low risk of bias, with limited information about many aspects of risk of bias, high drop out rates and issues regarding measurement instruments and the clinical usefulness of outcomes, which were often variously defined across trials. Overall, there was evidence that those treated with an antidepressant had lower depression severity scores and higher rates of response/remission than those on placebo. However, the size of these effects was small with a reduction in depression symptoms of 3.51 on a scale from 17 to 113 (14 trials; N = 2490; MD -3.51; 95% confidence interval (CI) -4.55 to -2.47). Remission rates increased from 380 per 1000 to 448 per 1000 for those treated with an antidepressant. There was evidence of an increased risk (58%) of suicide-related outcome for those on antidepressants compared with a placebo (17 trials; N = 3229; RR 1.58; 95% CI 1.02 to 2.45). This equates to an increased risk in a group with a median baseline risk from 25 in 1000 to 40 in 1000. Where rates of adverse events were reported, this was higher for those prescribed an antidepressant. There was no evidence that the magnitude of intervention effects (compared with placebo) were modified by individual drug class.

Authors’ conclusions

Caution is required in interpreting the results given the methodological limitations of the included trials in terms of internal and external validity. Further, the size and clinical meaningfulness of statistically significant results are uncertain. However, given the risks of untreated depression in terms of completed suicide and impacts on functioning, if a decision to use medication is agreed, then fluoxetine might be the medication of first choice given guideline recommendations. Clinicians need to keep in mind that there is evidence of an increased risk of suicide-related outcomes in those treated with antidepressant medications.

Plain language summary

Newer antidepressants for depression in children and adolescents

Depression is common in young people and can contribute to a variety of negative outcomes, such as poor academic functioning, difficulties in peer and family relationships, increases in substance use, and both attempted and completed suicide. This review contained 19 trials (with a total of 3353 participants) testing the effectiveness of newer generation antidepressants (these are antidepressants developed and used since tricyclic antidepressants were developed). These include the well-known selective serotonin reuptake inhibitors that have an impact primarily on the brain chemical called serotonin, as well as several other newer classes of antidepressants now being used, which aim to target noradrenaline and dopamine as well as serotonin and include selective norepinephrine reuptake inhibitors (SNRIs), norepinephrine reuptake inhibitors (NRIs), norepinephrine dopamine reuptake inhibitors (NDRIs), norepinephrine dopamine disinhbitors (NDDIs) and tetracyclic antidepressants (TeCAs)) for the treatment of depression in children and adolescents. Based on 14 of the trials (2490 participants in total), there was evidence that those treated with an antidepressant had lower depression severity scores than those on placebo, however, the size of this difference was small. Based on 17 trials (3229 participants in total), there was evidence of an increased risk (64%) of suicide-related outcomes for those on antidepressants compared with those given placebo. Where rates of adverse events were reported, this was higher for those prescribed an antidepressant. There was no evidence that one particular type of newer generation antidepressant had a larger effect than the others when compared to placebo.

It is unclear how meaningful the results regarding the effectiveness of these medications are in terms of a young person’s day-to-day functioning. Children and adolescents with other conditions (such as anxiety, substance use disorder or a conduct disorder) as well as depression, and those at risk of suicide, were often excluded from trials. However, these young people are more representative of the population who present to clinical services, therefore it is not possible to predict how they would respond to antidepressants. There was often insufficient information to judge the quality of the trials accurately. With these limitations, it is difficult to answer questions about the effectiveness and safety of antidepressants for treating depression in children and adolescents. Clinicians need to provide accurate information to children and adolescents, and their families, about the uncertainties regarding the benefits and risks of newer generation antidepressant medication as a treatment option for depression. If a decision to use medication is agreed then fluoxetine might be
the medication of first choice given guideline recommendations and, if used, the risk of suicide should be assessed and monitored particularly closely.

**SUMMARY OF FINDINGS FOR THE MAIN COMPARISON  [Explanation]**

### Second generation antidepressant versus placebo (by medication) for depressive disorders in children and adolescents

**Patient or population:** patients with depressive disorders in children and adolescents  
**Settings:** outpatient clinics  
**Intervention:** second generation antidepressant versus placebo (by medication)

**High quality:** Further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

**Low quality:** Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

**Very low quality:** We are very uncertain about the estimate.

---

1. Randomised trials were judged to be at a low risk of bias if they met the following criteria: a low risk of bias for sequence generation, allocation concealment, blinding of participants and assessors, incomplete outcome data, and selective outcome reporting. No trial met this criteria.

2. Low, median and high risk rates were derived from the lowest, the median and the highest placebo risk of suicide-related outcomes rate.

3. Randomised trials were judged to be at a low risk of bias if they met the following criteria: a low risk of bias for sequence generation, allocation concealment, blinding of participants and assessors, incomplete outcome data, and selective outcome reporting. No trial met this criteria.

4. The total number of events is less than 300.

5. Randomised trials were judged to be at a low risk of bias if they met the following criteria: a low risk of bias for sequence generation, allocation concealment, blinding of participants and assessors, incomplete outcome data, and selective outcome reporting. No trial met this criteria.
BACKGROUND

Description of the condition

Depressive disorders are common in young people (Kaufman 2001; Pine 1998) and are diagnosed according to the Diagnostic and Statistical Manual of Mental Disorders (DSM) or International Classification of Diseases (ICD) criteria, usually by a clinician conducting a structured or semi-structured diagnostic interview. The core features of depressive disorder include persistent low mood, loss of enjoyment in once pleasurable activities, and a negative view of oneself, the future and others. These features are generally similar in children, adolescents and adults (Carlson 1988; Marttunen 1998). The DSM includes criteria changes for children and adolescents such as the presence of irritability as an alternative to a depressed mood for this age group (Angold 1988; Essau 1999). Generally, anhedonia and psychomotor retardation are less common in the younger age group where clinical phenotypes can be indistinct with presentations including an admixture of anxiety, depressive and somatic symptoms (Axelson 2001; Rivas-Vasquez 2004). Low self esteem, concentration and thinking problems, and behaviour difficulties are more frequent (Carlson 1988). In adolescents the presentation of a depressive disorder may include substance abuse, antisocial behaviour, social withdrawal and academic failure (Masi 1998) with suicide attempts and ideation also common in adolescents (Marttunen 1998).

Prevalence estimates are higher in studies with a six to 12 rather than three-month time frame, with meta-analysis of prevalence estimates across different time points giving estimates of 2.8% (standard error (SE) 0.5%) for children, and 5.7% (SE 0.3%) for adolescents (Costello 2006). Life-time estimates range between 15% and 20% (Birmaher 1996). Incidence rates (rate of new diagnoses during a particular time period) range from 3.3% to 7.8% over a year for major depressive disorder (MDD) (Garrison 1997; Levinsohn 1998). The length of a depressive episode is often greater than 12 months: about 50% of children and adolescents remain clinically depressed at 12 months, and 20% to 40% at 24 months (Birmaher 1996; Harrington 2001; Kovacs 1984). Between 30% and 70% of cases have recurrences within five years, and many of these develop episodes into adult life (Fombonne 2001a; Fombonne 2001b; Levinsohn 1998; Richmond 2005; Weissman 1999). In the longer term, those children and adolescents who develop a recurrent or chronic disorder extending into adulthood are likely to suffer considerable disability and impairment, high rates of co-morbid disorders with poor academic functioning, difficulties in peer and family relationships, increases in substance use, and attempted and completed suicide (Brent 2002; Ehmeyer 2006; Fleming 1993; Harrington 1990; Levinsohn 1998; NHMRC 1997; Rao 1995).

The publication of the Global Burden of Disease (Murray 1996) included adolescents aged 15 to 18 years of age and showed depression as the fourth most important disease in the estimation of disease burden.

Description of the intervention

Overall there are relatively few long-term studies on depressive disorders in children and adolescents. Despite what is known about its prevalence and impacts, there is relatively little evidence for effective treatments or their impact on prognosis (NICE 2005). While a range of psychotherapies are effective (NICE 2005), adolescents’ response to psychotherapies may be weaker than adults (Cuipers 2005; Gloaguen 1998; Weisz 2006) and overall more research is required (NICE 2005).

Tricyclic antidepressants (TCAs) have not been shown to be an effective pharmacological treatment for depressive disorder in young people (Hazel 2002; Weller 2000). Newer generation antidepressants, especially selective serotonin reuptake inhibitors (SSRIs), have been increasingly used in recent decades (Vitiello 2006), with initial studies showing they were well tolerated (Cooper 1988). However, concerns about the increased risk of suicide and suicide attempt on SSRIs were first raised in 2003 (Healy 2003). Meta-analyses examining the risks of suicide-related behaviour and suicidal ideation combined (Hammad 2006) or separately (Dubicka 2006) have shown a consistent and modest increased risk of suicide for those taking SSRIs compared with placebo. Although debate about this issue is ongoing (e.g. Goodyer 2010; Hetrick 2010), the evidence for such risks has lead to action by regulatory bodies. The Committee on Safety of Medicines, Medicines and Healthcare Products Regulatory Agency (MHRA) in the UK (CSM 2004), the European Medicines Agency (EMEA 2005) and the Food and Drug Administration (FDA 2004) have cautioned practitioners in the use of SSRIs in children and adolescents, including an FDA ‘black box’ warning label issued 14 September 2004 (FDA 2004). In addition to SSRIs, several other classes of antidepressants are now being used, including selective norepinephrine reuptake inhibitors (SNRIs), norepinephrine reuptake inhibitors (NRIs), norepinephrine dopamine reuptake inhibitors (NDRIs), norepinephrine dopamine dis inhibitors (NDDIs) and tetracyclic antidepressants (TeCAs). SSRIs are sometimes referred to as ‘second generation’ antidepressants, and these newer additional classes are sometimes referred to as ‘third generation’ antidepressants. Rather than being a homogenous group based on mechanisms of action, however, third generation antidepressants are classed together because they are modified versions of first and second generation antidepressants (Olver 2001). Given the use of these classes of antidepressants, this updated version of the review includes these and throughout the review, second and third generation antidepressants are referred to as ‘newer generation’ antidepressants.

How the intervention might work

Antidepressant medication has evolved over the past 50 years. Until recently, a widely held belief was that dysfunction in serotonergic neurons and their targets may underlie depressive symptomatology (van Praag 1987). The dopaminergic system has also been
implicated, given its association with reward and appetitive motivation, whereby depression is characterised by a diminished ability to experience pleasure. Serotonin does have modulatory effects on dopamine, either increasing or decreasing its activity depending on the concomitant action of other neurotransmitters and the receptor subtype it is acting on. SSRIs cause an initial inhibition of the reuptake of serotonin (5-hydroxytryptamine, or 5-HT) (Lenox 2008), but while this effect occurs within hours of taking the medication, the clinical effects are not evident for some weeks. This suggests it may be the downstream effects of reuptake inhibition on gene expression and receptor regulation that are chiefly responsible for the clinical effects of SSRIs (Castren 2005). SSRIs also affect other neurotransmitters, including noradrenaline and dopamine (Healy 1997).

A third generation of antidepressants target the noradrenaline and dopamine systems to a greater degree than the SSRIs, though most also have an effect on the serotonergic system (Healy 1997). There is significant interplay between the monoaminergic systems, rendering efforts to reduce antidepressant action to their effects on a single system simplistic. This review refers to ‘newer generation antidepressants’ which encompasses both SSRIs and third generation antidepressant medication. It is unlikely that even within class these antidepressants will have similar effectiveness; similar to the multi-treatments meta-analysis by Cipriani 2009 we have pooled all individual compounds (rather than pooling within class) in order to look at whether the effect of newer antidepressants is modifiable by individual compound type (but we cannot assess comparative effectiveness given this is not a multi-treatments meta-analysis).

**Why it is important to do this review**

The American Academy of Child and Adolescent Psychiatrists, in response to the initial black box warnings, expressed concern about a stand that will deprive young people of effective treatment for a condition that carries with it considerable morbidity and mortality (Brent 2004; Findling 2004). Similarly, reviews examining the risks and benefits of antidepressants, most commonly SSRIs, consistently highlight the potentially serious consequences of untreated depression in children and adolescents. While modest treatment benefits have been shown for fluoxetine in children and adolescents (Hetrick 2007; Whittington 2004), there is contention about the effectiveness of other newer generation antidepressants. This review updates the previous version of the review to include not only SSRIs but newer antidepressants, to ensure information about all antidepressants is available and attempts to investigate issues of effectiveness and risk for children and adolescents with depression treated with these newer generation antidepressants.

**OBJECTIVES**

This update of the review aims to investigate not only the effects of SSRIs (as in the previous version) but also the effects of newer generation antidepressants compared with placebo, and factors which may modify the effects, in children and adolescents with a diagnosed depressive disorder. Specific objectives are to:

1. estimate the pooled effect of newer generation antidepressants on depression, function and adverse outcomes and whether this effect is modified by drug and age (children versus adolescents);

2. estimate the effect of each newer generation antidepressant, compared with placebo, on depression, function and adverse outcomes.

Results from this review do not address questions of comparative effectiveness of each of the newer generation drugs. However, in a future review we plan to undertake a multiple-treatments meta-analysis comparing the effectiveness of each individual drug which meets the scope of the current review.

**METHODS**

**Criteria for considering studies for this review**

**Types of studies**

Three types of published (including internet publication) and unpublished trials were eligible for inclusion in the review: parallel-group individually randomised controlled trials (RCTs), crossover trials (where cross-over trials with less than one-week washout are treated as parallel-group trials including only the first period) and cluster trials. In the original review only SSRIs were included; however, including newer antidepressants was considered important to ensure information about all antidepressants was available. Information on adverse effects from other types of studies were not included in the review. We applied no language restrictions.

**Types of participants**

Children and adolescents aged 6 to 18 years old, both in and outpatients, who were diagnosed by a clinician and met DSM (APA 2000) or ICD (WHO 2004) criteria for a primary diagnosis of depressive disorder in its acute phase were eligible for inclusion. In the original version of the review, we intended to include trials of sub-syndromal depressive disorders. However, in this update we restricted the inclusion criteria to depressive disorder given that guidelines for the treatment of youth depression do not recommend medication is used in this group (McDermott 2011; NICE 2005).
Trials where both adults and children/adolescents were treated were eligible for inclusion if data on the children/adolescents could be extracted separately or obtained from trial authors. Trials that did not exclude participants with co-morbid conditions secondary to a depressive disorder were eligible for inclusion and, if included in the future, a separate analysis is planned for those with only depressive disorder and those with a depressive disorder and a co-morbid condition(s). Trials of children and adolescents with an intellectual quotient (IQ) of less than 70, organic brain injury or serious medical condition (that might result in risk to the participant or compliance issues) were not eligible for inclusion.

**Types of interventions**

In this updated version of the review, trials were eligible for inclusion if they compared the effectiveness of newer generation antidepressants with a placebo. It was considered important to include all newer antidepressants to ensure information about all antidepressants was available. These antidepressants were those consistent with the medications included in the equivalent Cochrane Depression, Anxiety and Neurosis (CCDAN) Group Meta-Analysis of New Generation Antidepressants (MANGA) reviews for adult depressive disorders (Churchill 2010; Cipriani 2005; Cipriani 2009a; Cipriani 2009b; Cipriani 2009c; Cipriani 2010; Guiana 2010; Imperatore 2009; Nakagawa 2009; Nosè 2009; Omori 2010; Watanabe 2011). We have grouped them according to class as follows.

- **Selective serotonin reuptake inhibitors (SNRIs)**: fluoxetine, fluvoxamine, sertraline, paroxetine, escitalopram, citalopram
- **Selective norepinephrine reuptake inhibitors (SNRIs)**: venlafaxine, duloxetine, desvenlafaxine, milnacipran
- **Norepinephrine dopamine reuptake inhibitors (NDRIs)**: reboxetine
- **Norepinephrine dopamine reuptake inhibitors (NDRIs)**: bupropion
- **Norepinephrine dopamine dis inhibitors (NDDIs)**: agomelatine
- **Tetracyclic antidepressants (TeCAs)**: mirtazapine

We placed no restrictions on the dose or pattern of administering these antidepressants for the purposes of inclusion in the review. Trials where newer generation antidepressants were used in combination with another pharmacological intervention or psychological intervention exclusively were not eligible for inclusion. Trials with multiple comparison arms were eligible for inclusion, with only data from relevant treatment arms to be extracted.

**Types of outcome measures**

**Primary outcomes**

1. Depressive disorder according to DSM or ICD criteria and established by a clinician conducting a structured or semi-structured diagnostic interview such as the Schedule for Affective Disorders and Schizophrenia for School Aged Children, Present Episode Version (K-SADS-P) (Chambers 1985). This was chosen as the most robust approach to establishing the resolution of a depressive episode.
2. Suicide completion established via recording of adverse outcome within the trial period or by medical record or direct inquiry with appropriate contact person at follow-up.

**Secondary outcomes**

1. **Efficacy outcomes**

   1.1 Depression symptom severity (clinician-rated) using the Children's Depression Rating Scale (CDRS-R). This outcome was chosen on the basis of a hierarchy of rating scales based on psychometric properties and appropriateness for use with children and adolescents and for consistency of use across trials (the most commonly used tool) (see Appendix 1). The CDRS-R was adapted for children and adolescents from the Hamilton Depression Rating Scale (HAM-D), a tool validated and commonly used in adult populations (Brooks 2001). Both the CDRS-R and HAM-D have good reliability and validity (Brooks 2001). The Montgomery-Asberg Depression Rating Scale (MADRS) was also based on the HAM-D but designed to better assess sensitivity to change. However, it was not designed specifically for children and adolescents (Brooks 2001)

   1.2. Remission or response as defined by trialists. ‘Remission’ and ‘response’ are commonly defined by dichotomising a continuous measure of clinician-rated depression symptoms. The labelling of remission and response varied across trials, with the labelling being different even although the cut-point was the same. For consistency across trials, we chose the most commonly reported cut-point, which was generally referred to as ‘remission’ (CDRS-R ≤ 28). When ‘remission’ was not reported, we used ‘response’ if available (we have used last observation carried forward (LOCF) data in the first instance (see Dealing with missing data) so that if remission was only available from observed case (OC) data but response data were available from LOCF data, we have used response data).

   The outcome represents some measure of improvement, but there are difficulties in interpretation because of the inconsistencies in scales and cut-points (Hetrick 2010).

   We have chosen to include both continuous and dichotomised measures of clinician-rated depression symptoms (outcomes 1.1 and 1.2/1.3 respectively), since there are advantages and disadvantages to each. Responder analyses (based on the dichotomised continuous outcomes) are well known to be problematic (Kieser 2004), with arbitrariness in the choice of cut-point, loss of power resulting from the dichotomisation (Altman 2006) and difficulties in interpretation (as outlined above). However, synthesising continuous outcomes is not without its difficulties. The scales used to measure depression symptoms vary across trials; there is inconsistency in the analytical methods employed (e.g. analyses of change scores, regression models), which can preclude the use of the stan-
and Controlled-T rials.com have been chosen, again to maximise ClinicalT rials.gov can be found on the Group’s website.

Electronic searches

Searches for the original review

The original searches of MEDLINE, EMBASE and PsycINFO were undertaken to October 2005 and of CENTRAL (the Cochrane Central Register of Controlled Trials) to Issue 2, 2004 (Appendix 2). CCDAN’s Specialized Register, the CCDANCTR, was also searched at this time by the Trials Search Co-ordinator using the following terms:

Diagnosis = (Depress* or Dysthymi*) AND Intervention = (‘Selective Serotonin Reuptake Inhibitors’ or Alaproclate or Citalopram or Escitalopram or Fluoxetine or Fluvoxamine or Paroxetine or Sertraline) AND Age Group = (Child or Adolescent) Other databases searched were the National Research Register (now archived), ClinicalTrials.gov and Controlled-T rials.com. Additionally, the trial databases of pharmaceutical companies were searched.

Updated searches

Update searches were conducted on the CCDANCTR (to 28 October 2011) using additional terms for newer generation antidepressants:

CCDANCTR-Studies Register

Diagnosis = (Depress* or Dysthymi*) AND Intervention = (‘Selective Serotonin Reuptake Inhibitors’ or Agomelatine or Alaproclate or Bupropion or Citalopram or Desvenlafaxine or Duloxetine or Escitalopram or Fluoxetine or Fluvoxamine or Milnacipran or Mirtazapine or Paroxetine or Reboxetine or Sertraline or Venlafaxine) AND Age Group = (child* or adolescent* or “not stated” or unclear)

CCDANCTR-References Register

The CCDANCTR-References register was searched using a more sensitive set of terms to identify additional untagged/uncoded references:

Title/Abstract/Keywords = (depress* or dysthymi*) AND Free-Text=(Agomelatine or Alaproclate or Bupropion or Citalopram or Desvenlafaxine or Duloxetine or Escitalopram or Fluoxetine or Fluvoxamine or Milnacipran or Mirtazapine or Paroxetine or Reboxetine or Sertraline or Venlafaxine or (serotonin and (uptake or reuptake or re-uptake)) or SSRI*) AND Free-Text=(adolesc* or child* or boys or girls or juvenil* or minors or paediatric* or pediatric* or pubescen* or school* or students or teen* or young or youth*)

Search methods for identification of studies

CCDAN’s Specialised Register (CCDANCTR)

searches for the original review

The Cochrane Depression, Anxiety and Neurosis Group (CCDAN) maintain two clinical trials registers at their editorial base in Bristol, UK, a references register and a studies-based register. The CCDANCTR-References Register contains over 30,000 reports of randomised controlled trials in depression, anxiety and neurosis. Approximately 65% of these references have been tagged to individual, coded trials. The coded trials are held in the CCDANCTR-Studies Register and records are linked between the two registers through the use of unique Study ID tags. Coding of trials is based on the EU-Psi coding manual. Please contact the CCDAN Trials Search Co-ordinator for further details.

Reports of trials for inclusion in the Group’s registers are collated from routine (weekly), generic searches of MEDLINE (1950 -), EMBASE (1974 -) and PsycINFO (1967 -); quarterly searches of the Cochrane Central Register of Controlled Trials (CENTRAL) and review-specific searches of additional databases. Reports of trials are also sourced from international trials registers c/o the World Health Organization’s trials portal (ICTRP), ClinicalTrials.gov, drug companies, the handsearching of key journals, conference proceedings and other (non Cochrane) systematic reviews and meta-analyses. Details of CCDAN’s generic search strategies can be found on the Group’s website.
An additional search of international trials registries was conducted via the World Health Organization's trial portal (ICTRP), which at the time covered the following data providers:

- Australian New Zealand Clinical Trials Registry
- ClinicalTrials.gov
- ISRCTN (ControlledTrials.com)
- Chinese Clinical Trial Registry
- Clinical Trials Registry - India
- German Clinical Trials Register
- Iranian Registry of Clinical Trials
- Japan Primary Registries Network
- Pan African Clinical Trial Registry
- Sri Lanka Clinical Trials Registry
- Netherlands National Trial Register

Searching other resources

Reference lists
We screened the reference lists of included articles and other reviews retrieved in the search.

Handsearches
We searched pharmaceutical company websites, including Eli Lilly and Company, Forest Laboratories, Merck Pharmaceuticals, Lundbeck Pharmaceuticals, GlaxoSmithKline, Brystol-Myers Squibb and Pfizer Pharmaceuticals (the company Wyeth that was searched in original review has been subsumed by Pfizer).

Conference abstracts
We searched conference abstracts for the American Academy of Child and Adolescent Psychiatry (2003 to 2005) for the original review.

Personal communication
We consulted the authors of the included trials and other individuals with expertise in this field to find out if they knew of any potentially relevant published or unpublished RCTs/controlled clinical trials (CCTs).

Data collection and analysis

Selection of studies
Two review authors (MS and GC) performed the selection of trials for inclusion in the updated review independently after employing the search strategy described above. Where a title or abstract appeared to describe a trial eligible for inclusion, we obtained the full article to assess whether it met the inclusion criteria. We have reported the reasons for exclusion of trials in the Characteristics of excluded studies tables.

Data extraction and management
Two review authors (SH and GC) independently extracted information on each trial, including 'Risk of bias' criteria and details of participants, interventions, comparisons, outcomes and potential modifying factors (age, individual drug type). Discrepancies were resolved by a third review author (JM). When estimates of treatment effect or standard errors were not directly reported, we calculated these, where possible, through algebraic manipulation of available statistics (e.g. means, confidence interval limits, exact P values).

For the first version of the review we decided post hoc to extract suicide-related outcomes from the Medicines and Healthcare Products Regulatory Agency (MHRA) rather than from the individual trial reports retrieved in the search for the current review. The MHRA has produced a web-based report (www.mhra.gov.uk/) that summarises the results of the majority of the trials included in the original review. We used two additional reports, one on suicide-related outcomes (Hammad 2004) and one on trial characteristics (Dubitsky 2004) giving details of outcomes for 25 SSRI trials for a range of disorders in children and adolescents. For this version of the review, we have again used the data from the FDA report of suicide-related outcomes where it is available and where it is not, extracted data as similar in definition to that used in this report from individual trials.

Assessment of risk of bias in included studies
In the original review we assessed the risk of bias in the included trials using the quality of trials ratings devised by Moncrieff and colleagues (Moncrieff 2001). For this update we used the Cochrane Collaboration’s new ‘Risk of bias’ tool (Higgins 2009). Specifically, for each trial, we assessed the domains sequence generation, allocation concealment, blinding of participants and assessors (separately for efficacy outcomes and adverse outcomes), incomplete outcome data and selective reporting. We sought to assess trial protocols where published/available in the first instance and also sought clarification from trial authors in the case of suspicion of reporting bias) and any other sources of possible bias that which might affect the outcome of the trial results. We judged each domain as being at a low, high or unclear risk of bias. We also extracted relevant text which underpinned our judgement and this is presented in the ‘Risk of bias’ tables in Characteristics of included studies.
Two review authors (SH and GC) performed all assessments of the quality of trials independently, with discrepancies resolved by JM.

**Measures of treatment effect**

For dichotomous outcomes, we measured treatment effects using risk ratios (RR) (e.g. response rates and adverse effects). In the original version of this review, a post hoc decision was made not to calculate number needed to treat to benefit (NNTB) and number needed to treat to harm (NNTH) primarily because these effect measures have undesirable statistical properties and can be difficult to interpret (Julious 2005; Wisloff 2011). Instead, in our Summary of findings for the main comparison, we present estimates of risk difference, in addition to risk ratios, to aid interpretation, for a range of control group rates (lowest, highest and median rate derived from the placebo groups).

For each drug, we estimated the risk ratio of experiencing adverse events (where a count of any adverse event was reported). However, given inconsistencies in data collection of these events between trials, the risk ratios may not be comparable between drugs; therefore, information about adverse events is also presented in Table 4.

For continuous outcomes (such as clinician-rated depression symptom severity), we have used the mean difference (MD). In the majority of trials, multiple linear regression models had been fitted, and ‘adjusted’ estimates of treatment effects from these models were reported (often as least square means or least square mean differences). These models adjusted for varying factors such as age, sex, investigator site and baseline of the outcome (details available from the review authors). We were not able to use the standardised mean difference (SMD) where the same outcome was measured across trials, but using a different scale because there was inconsistency in the analytical methods employed (e.g. analyses of final values, change scores and regression models).

We presented data that could not be meta-analysed, such as information on co-morbidity, and treatment effects for trials that have used different scales than our chosen scale, in tables.

**Unit of analysis issues**

There were no trials with more than one intervention arm compared with the placebo group. In future updates, if this occurs, we will compare data from each arm with the placebo group. We will divide the sample size in the placebo arm by the number of intervention arms included in the meta-analysis to preclude multiple counting of trial participants. While this approach offers some solution, it does not completely account for the correlation arising from using the same set of participants in the placebo comparison group (Chapter 16, Higgins 2009).

No cross-over trials were included, but if they are located in future updates, if the appropriate data for a paired t-test analysis is not available and cannot be obtained from trial authors, we will impute missing statistics (e.g. missing standard deviation, correlation) using data available from other trials included within the meta-analysis, or trials outside the meta-analysis (Chapter 16, Higgins 2009; Elbourne 2002). We will use sensitivity analyses to assess the robustness of the pooled treatment effect to assumptions made regarding missing statistics.

If cluster-RCTs are included in future updates, which have not appropriately adjusted for the correlation between participants within clusters, we will contact trial authors to obtain an estimate of the intra-cluster correlation (ICC), or imputed using estimates from the other included trials or from similar external trials. We will inflate the trial standard errors (Chapter 16 Higgins 2009).

**Dealing with missing data**

We sought additional data from the principal authors and pharmaceutical companies of trials (the latter approached by the CC-DAN group on our behalf) (and the National Institutes for Mental Health (NIMH) in the case TADS 2004) that met the eligibility criteria where the data were missing, or were in a form unsuitable for meta-analysis. We also searched the pharmaceutical company websites for additional data on included trials.

Most trials used the last observation carried forward (LOCF) method of data imputation for the majority of outcomes, that is, the last observed value for a participant lost to follow-up is assigned as the follow-up value. We chose to pool LOCF data (rather than mix LOCF and OC data).

The observed case remission/response data were sought since we planned to investigate the effect of missing data using the “informative missingness odds ratios” (IMOR) framework (Higgins 2008). However, only a few trials reported observed case data for this outcome (paroxetine trials, sertraline trials, one trial of citalopram and one small trial of fluoxetine) and we were unsuccessful in obtaining observed case data for the other trials. We have undertaken sensitivity analysis using OC data where available. Estimates of treatment effect based on either LOCF or OC data can result in serious bias (Sterne 2009).

In some trials, least squares means and their standard errors were reported from regression models by treatment group, but no contrast between groups was reported. For these trials, we estimated the variance of the treatment effect by summing the square of the standard errors in each treatment group. There may be some inaccuracy in this approach when there is imbalance in the covariates being adjusted for.

**Assessment of heterogeneity**

We assessed heterogeneity of intervention effects by visually inspecting the overlap of confidence intervals on the forest plots, tested for heterogeneity using the Chi² test, and quantified heterogeneity using the I² statistic (Higgins 2003). Categories suggested in Higgins 2009 (Chapter 9) are used to help interpret the degree of heterogeneity (0% to 40% might not be important; 30% to
60% may represent moderate heterogeneity; 50% to 90% may represent substantial heterogeneity; 75% to 100% considerable heterogeneity). We calculated 95% confidence intervals for values of I² using the non central Chi² approximation implemented in the Stata module heterogi (Orsini 2006).

Assessment of reporting biases
We investigated the potential for small-study effects using funnel plots and contour-enhanced funnel plots. Contour-enhanced funnel plots aid in determining if funnel plot asymmetry is due to publication bias or other factors (Peters 2008; Sterne 2011). The outcomes ‘remission/response’ and suicide-related behaviour were chosen since they were available for the majority of included trials. We have used the statistical test proposed by Harbord et al (Harbord 2006) (as implemented in the Stata module metabias (Harbord 2009)) to test for small-study effects.

Data synthesis
We pooled estimates of treatment effect using inverse variance weighting, using a random-effects model. DerSimonian and Laird’s method of moments estimator was used to estimate between-trial variance (DerSimonian 1986). We made the decision to use a random-effects model since there was expected clinical diversity in the antidepressant medications, given their differing actions on various monoaminergic systems. Where trials did not report data suitable for meta-analysis, treatment estimates or raw data (as appropriate for each outcome) for each individual study are reported in additional tables. We judged randomised trials to be at a low risk of bias if they met the following criteria: a low risk of bias for sequence generation, allocation concealment, blinding of participants and assessors, incomplete outcome data, and selective outcome reporting. We summarised the risk of bias across the trials in the text of the review. As part of the sensitivity analyses, we present meta-analyses of trials that are judged to be at a low risk of bias for the outcomes depression symptom severity (CDRS-R), remission/response and suicide-related outcome.

Subgroup analysis and investigation of heterogeneity
We undertook a subgroup analysis based on the individual compounds to examine if the effect of newer generation antidepressants was modified by individual drug. Clinically, these drugs are used individually, with clinicians often trying to make a decision about which one is best to use for a particular individual. There is evidence that children and adolescents may respond differently to pharmacological intervention, e.g. oral tricyclic antidepressants versus placebo significantly reduce symptoms in adolescents but not in children (Hazell 2002). For this reason we conducted subgroup analyses by age, where children and adolescents were defined as those aged approximately 6 to 12 and 13 to 18 years respectively (Characteristics of included studies). When estimates of treatment effect were not presented for children and adolescents separately, we created another subgroup which contained both children and adolescents.

In the first version of the review, we had planned a priori to undertake subgroup analyses based on depressive disorder (major versus dysthymic disorder, depressive disorder not otherwise specified and ‘double depression’), sex and co-morbidity. However, due to limited data, we did not carry out analyses on these subgroups, nor was it possible in this update.

Sensitivity analysis
In the original review, we did not carry out pre-planned sensitivity analyses based on pharmaceutical funding (financial support of trials by pharmaceutical companies has been shown to influence trial results (Schott 2010)) and inclusion criteria (clinical diagnosis versus depression rating scales) since the majority of trials were pharmaceutically funded, and no trials used rating scales as inclusion criteria. We did not undertake a pre-planned sensitivity analysis based on attrition rates since there were reasonably high attrition rates in all included RCTs (19% to 38%, Table 5).

For this version of the review, we undertook sensitivity analyses based on the assessment of risk of bias in the trials (see Data synthesis), whereby trials deemed to be at a high risk of bias were excluded from the analysis.

We undertook sensitivity analysis based on methods of imputation for missing data used by trial authors such that we substituted LOCF data for OC data for the outcome ‘remission/response’. Finally, given the inclusion in this review of third generation antidepressants that have a different proposed mechanism of action from SSRIs, we have undertaken sensitivity analysis on the basis of drug class, excluding third generation antidepressants from the overall pooled analysis.

Timeline
Ongoing updates of this review will usually be submitted for editorial review within two years of publication of the review.

RESULTS

Description of studies
See: Characteristics of included studies; Characteristics of excluded studies; Characteristics of ongoing studies.
Results of the search

Twelve trials were included in the original review (Hetrick 2007), with data extracted from 10 trials and pooled in one or more meta-analyses. As our inclusion criteria have been expanded to include newer classes of antidepressants, four trials excluded from the original review have been included in this version of the review (Emslie 2007 Trial 1; Emslie 2007 Trial 2; Mirtazapine Trial 1; Mirtazapine Trial 2).

In this update, 530 trials were retrieved in the search, of which 408 were excluded on the basis of title and abstract. We attempted to retrieve 122 full-text articles for full inspection. Forty publications could not be located (the majority of these were conference proceedings that had not been subsequently published). Of the 82 that were obtained, 64 were either already included trials or were secondary publications from already included trials (35 of these were for TADS 2004 and are not listed under the main reference for this trial). Seven new trials were included, four of which are ongoing trials (Duloxetine NCT00849693; Duloxetine NCT00849901; Glod 2004; Solvay NCT00353028), leaving a total of 19 trials included in this updated version of the review (Figure 1). In addition, seven studies were newly excluded (see Excluded studies).
Figure 1. Study flow diagram.

530 records identified through database searching

0 additional records identified through other sources; 12 already included studies; 8 already excluded studies (4 of which were included in this update of the review)

530 records after duplicates removed

530 records screened

408 records excluded

7 full-text articles were newly excluded (2 did not have a pure newer generation antidepressant or placebo treatment arm, 2 focused on co-morbid substance use, 1 was due to the intervention not being an included antidepressant and 2 were not RCTs); 64 articles were already included or were secondary publications to already included trials; 40 could not be located.

122 full-text articles sought for assessment of eligibility

19 studies included in qualitative synthesis

18 studies included in at least 1 quantitative synthesis (meta-analysis)
The three trials newly included from the updated search include: A new trial on fluoxetine (Almeida-Montes 2005). This trial was published in Spanish and data extracted by a colleague who speaks Spanish, with additional data sought via this colleague. A new trial of escitalopram (Emslie 2009) and a new trial of paroxetine (Paroxetine Trial 1).

In the original review, two trials were initially unpublished, and in this update they are referred to by their subsequent publication trial identification: Berard 2006 (was Milin 2004); Emslie 2006 (was paroxetine study 3).

For the included trials, we had retrieved additional reports during preparation of the original review, including the web-based report of the Medicines and Healthcare Product Regulatory Agency (MHRA), summarising the majority of clinical trials on SSRIs for major depressive disorder in children and adolescents at the time. When we wrote to trial authors for additional data during preparation of the original review, in many cases trial authors did not have access to any additional data. We accessed the trial reports published online by SmithKline Beecham on paroxetine (Berard 2006; Emslie 2006; Keller 2001) (http://www.gsk.com/media/paroxetine.htm). For one paroxetine trial (Paroxetine Trial 1) we only had access to a brief trial report from this website. We had also accessed trial reports published online by Forest Laboratories for escitalopram and citalopram and for this update located the report for a newly located trial of escitalopram. Eli Lilly provided additional data for a trial on fluoxetine (Emslie 2002) during preparation of the original review. For this update, the trial authors for this trial and for Emslie 1997 were able to provide additional data in response to our requests. For this update we accessed trial reports of venlafaxine from CCDAN who had accessed them from Pfizer.

Two published trial reports include the results of two trials Wagner Trial 1&2 (2003) and Emslie 2007. Data for the individual trials for Wagner Trial 1&2 (2003) were only available from the MHRA report. Emslie 2007 provides some data separately for each of the two trials included in the publication. There was no published report for the mirtazapine trials; data were available from the MHRA report and from two reports to regulatory agencies. The trial by Simeon was discontinued early due to slow enrolment, with some information about the trial from the written report and some from the MHRA report (Dubitsky 2004).

Included studies

Design
The trials were all individual patient parallel-group randomised trials. All were multicentre with the exception of Almeida-Montes 2005, Emslie 1997 and Simeon 1990. Most trials had two arms, comparing a newer generation antidepressant with placebo. The Treatment for Adolescents with Depression trial (TADS 2004) includes four comparison groups: an SSRI group, a cognitive behaviour group (CBT), a combined SSRI and CBT group and a placebo group. We only extracted data from the SSRI and placebo groups. The Keller 2001 study included three comparison groups: a TCA group, an SSRI group and a placebo group. We only extracted data from the SSRI and placebo groups.

Sample sizes
The number of participants randomised to the relevant arms in these trials ranged from 23 to 367 (median 188).

Setting
The included trials were undertaken in many countries (Denmark, Estonia, Germany, Norway, Sweden, Switzerland, Argentina, Belgium, Holland, Italy, Japan, Mexico, South Africa, Spain, United Arab Emirates, UK, India, Costa Rica, USA, Canada). Most of the trials gave little information on their recruitment strategies. Of those that did, Emslie 2002, TADS 2004 and Mirtazapine Trial 1 & 2 used media advertising. Emslie 1997 stated that media recruitment was not used (Characteristics of included studies).

Only two trials (Simeon 1990; Von Knorring 2006) stated that inpatients were included, although the MHRA report (Dubitsky 2004) states that Simeon 1990 only included outpatients. We have attempted to contact this author but have not had a reply.

Participants
There were six trials in adolescents only (Berard 2006; Emslie 2009; Keller 2001; Simeon 1990 TADS 2004; Von Knorrning 2006) with an age range of 12 or 13 to 17 or 18, and 13 trials of children and adolescents (Almeida-Montes 2005; Emslie 1997; Emslie 2002; Emslie 2006; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Mirtazapine Trial 1 & 2; Paroxetine Trial 1; Wagner 2004; Wagner 2004; Wagner Trial 1&2 (2003)) with a lower age limit of between six to eight years. The mean age ranged from 14.4 to 16.0 years and 11.5 to 13.3 years in the adolescent, and child and adolescent, trials respectively (Characteristics of included studies). There were similar proportions of females and males in Emslie 2002; similar numbers but slightly more males than females in five trials (Emslie 1997; Emslie 2006; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Mirtazapine Trial 1); and similar numbers but slightly more females than males in two trials (Mirtazapine Trial 2; Wagner 2006). The proportion of females was greater than males but balanced across groups in one trial (Emslie 2009). There were nearly
twice as many females in two trials (Keller 2001; Berard 2006). In Wagner 2004 and Wagner Trial 1 (two trials reported together), there was imbalance in the proportion of females between groups, with a greater proportion of females in the treatment group; in Paroxetine Trial 1 the proportion of females was greater in the placebo group. The TADS 2004 and Simeon 1990 trials did not provide information on sex by treatment arm but overall there were somewhat more females than males. Two trials provided no information on sex (Almeida-Montes 2005; Von Knorring 2006) (Characteristics of included studies).

All trials were of major depressive disorder with three trials basing diagnoses on DSM-III or DSM-III-R criteria (Emslie 1997; Keller 2001; Simeon 1990) and the remainder on DSM-IV criteria. The majority used a semi-structured clinical interview (K-SADS and Almeida-Montes 2005 used the MINI-KID); one trial gave no information (Paroxetine Trial 1). Von Knorring 2006, in contrast to all the other trials, used only a five-minute clinical interview with parents. In addition to a diagnostic interview, the majority of trials (except Emslie 2006) used a cut-off score on a measure of depression symptom severity to establish eligibility. Emslie 1997; Emslie 2002; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Mirtazapine Trial 1 & 2; Wagner 2006 and Wagner 2004 used a cut-off of greater than 40 on the CDRS-R; while for Emslie 2009; Paroxetine Trial 1; TADS 2004 and Wagner Trial 1 the cut-off was 45. In Von Knorring 2006 the Children’s Depression Inventory (CDI) was used with cut-offs greater than 21 and 16 for girls and boys respectively. A score greater than 12 or 20 on the HAM-D scale was used in Keller 2001 and Simeon 1990 respectively, and a score greater than 16 on the MADRS scale was used in Berard 2006. Almeida-Montes 2005 used a score greater than 13 on the DSDR. Some trials also used a measure of functioning to confirm diagnosis (Berard 2006; Keller 2001; Mirtazapine Trial 1 & 2; Von Knorring 2006; Wagner Trial 1). Some trials included a screening process that was undertaken over a period of one to three weeks (Emslie 1997; Emslie 2002; Emslie 2006; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Emslie 2009; Keller 2001; Paroxetine Trial 1; TADS 2004; Wagner Trial 1). A report by the MHRA described the process as more extensive for three of these trials (Emslie 1997; Emslie 2002; Keller 2001) but did not describe what this meant. Further investigation revealed a screening process that included up to three independent diagnostic interviews, taking place over a period of up to three weeks. In 11 trials all participants were treated with placebo for a lead-in period and those whose depressive disorder improved during this time were excluded (Almeida-Montes 2005; Berard 2006; Emslie 1997; Emslie 2002; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Emslie 2009; Paroxetine Trial 1; Simeon 1990; Wagner 2004; Wagner 2006).

Authors of all trial reports, except two (Almeida-Montes 2005; Simeon 1990), describe depression symptom severity at baseline for the treatment and placebo groups. Mean severity scores at baseline from the individual trials range from 47.6 to 65.5 on the CDRS-R (range 17 to 113) (equivalent to T-Scores that correspond to a depressive disorder being likely or very likely to be confirmed) and from 25.9 to 32.5 on the K-SADS nine-item depression score (range 9 to 56) (Keller 2001; Von Knorring 2006) and 25.9 on the MADRS (Berard 2006). For all trials, there was no clinically important imbalance between treatment groups in depression symptom severity at baseline. Clinical Global Impression (CGI) scores were reported in 11 trials and ranged from a mean of 3.9 to 4.8 (with a median of four being reported in Emslie 2006), which is in the moderately ill range. Of those trials that reported on the percentage of young people who were experiencing a first episode of depression (12 trials), the rates varied from 42.7% to 95% in the intervention group and 42.8% to 95% in the placebo group. The length of the current episode was reported variously in 10 trials and ranged from approximately 15 weeks to 108 weeks in the intervention group and 14 to 100 weeks in the placebo group, with the majority of trials reporting episode lengths of over 35 weeks.

Seven trials provided no detail about the co-morbid conditions of participants (Almeida-Montes 2005; Emslie 2007; Mirtazapine Trial 1 & 2; Paroxetine Trial 1; Simeon 1990; Von Knorring 2006). Wagner Trial 1 & 2 (2003) provided data for sertraline and placebo groups combined for both trials combined. In this trial the co-morbid conditions that were most common (> 5%) were anxiety, phobic disorder, adjustment reaction and ODD. Five trials (Emslie 1997; Emslie 2006; Emslie 2009; Keller 2001; TADS 2004) provided data on the number of young people who had any co-morbid condition with rates very variable across trials (Emslie 2006 and Emslie 2009 having the lowest rates), ranging from 12.9% to 85.4% in the intervention arms and 16.6% to 77.1% in the placebo arms (see Table 6).

In eight trials the percentage of young people experiencing various different types of co-morbid conditions was provided and has been presented in Table 6. The percentages vary markedly between trials, with Emslie 1997; Emslie 2002; Keller 2001 and TADS 2004 having the highest rates of various co-morbid conditions. It is clear from research that co-morbidity may affect the clinical outcome (Birmaher 1996; Kovacs 1989); however it is difficult to examine this, given the non standard way in which co-morbidity is reported and because some co-morbid disorders form part of the exclusion criteria in some trials.

In all trials exclusion criteria included psychotic features or disorder, and all but two excluded substance abuse or dependence (Paroxetine Trial 1; Wagner Trial 1 & 2 (2003), who did not state that substance abuse or dependence was excluded). In all but seven trials (Almeida-Montes 2005; Emslie 2006; Paroxetine Trial 1; Simeon 1990; TADS 2004; Wagner Trial 1 & 2 (2003)) anorexia nervosa and bulimia nervosa were excluded; in all but nine trials (Almeida-Montes 2005; Emslie 1997; Emslie 2002; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Mirtazapine Trial 1 & 2; Paroxetine Trial 1; Simeon 1990) pervasive developmental disorders were excluded. Externalising disorders (disruptive behaviour disorder,
Oppositional Defiant Disorder (ODD) and Conduct Disorder (CD) and/or attention deficit-hyperactivity disorder (ADHD) were excluded in 10 trials (Almeida-Montes 2005; Berard 2006; Emslie 2009; Emslie 2007 Trial 1; Emslie 2007 Trial 2; TADS 2004; Von Knorring 2006; Wagner Trial 1&2 (2003); Wagner 2004; Wagner 2006). Obsessive compulsive disorder was excluded from all but two trials (Almeida-Montes 2005; Emslie 1997; Emslie 2002; Emslie 2006; Paroxetine Trial 1; Simeon 1990; TADS 2004; Von Knorring 2006; Wagner 2004; Wagner 2006). Other anxiety disorders included were post-traumatic stress disorder (Berard 2006; Emslie 2009; Keller 2001; Wagner 2004; Wagner 2006) and panic disorder (Berard 2006; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Wagner Trial 1&2 (2003)), social phobia (Berard 2006) and ‘severe anxiety disorder’ (Almeida-Montes 2005).

Bipolar was excluded from all but two trials (Berard 2006; Simeon 1990) and patients with a first-degree relative with a history of bipolar were excluded from seven trials (Emslie 1997; Emslie 2002; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Emslie 2009; Mirtazapine Trial 1 & 2).

Participants who were considered at risk for suicide at baseline were specifically excluded in all but three trials (Emslie 1997; Paroxetine Trial 1 for which no statement was explicitly made; Von Knorring 2006). The method to define risk varied across trials; some gave no definition of ‘serious suicidality risk’ (Emslie 2002; Emslie 2006; Simeon 1990) or acute suicidality (Emslie 2007 Trial 1; Emslie 2007 Trial 2) or defined it as “in the opinion of the investigator” (Almeida-Montes 2005); previous attempt was exclusionary in nine trials (Emslie 2009; Keller 2001; Mirtazapine Trial 1 & 2; TADS 2004; Wagner Trial 1&2 (2003); Wagner 2004; Wagner 2006); one trial stated that attempt was not exclusionary, only current suicidal ideation with intent or plan (Berard 2006), although this was contradicted by the FDA report (Hammad 2004) that stated that a history of suicidal ideation was not an exclusion criteria in any of the trials included in its report. Along with suicide attempt, Keller 2001 also stated those with serious suicidal ideation with intent or a specific plan were excluded. Subsequent to the report by Hammad 2004, two trials have also included suicidal ideation as an exclusion criteria: TADS 2004 states that “clear intent or an active plan to commit suicide, or suicidal ideation with a disorganized family unable to guarantee adequate safety monitoring” and Emslie 2009 states that those who had “active suicidal ideation” was exclusionary. The FDA carried out a stratified analysis of those trials included at the time based on history of suicide attempt or ideation to investigate if risk of suicide attempt or ideation for those receiving SSRIs varied by stratum. They concluded that there was no evidence of this (Hammad 2004).

Interventions

In the SSRI class, there were four trials of paroxetine (Berard 2006; Emslie 2006; Keller 2001; Paroxetine Trial 1), five trials of fluoxe-

Outcomes

In the SNRI class there were two trials of venlafaxine (both reported in Emslie 2007), and in the TeCA class there were two trials of mirtazapine (Mirtazapine Trial 1 & 2).

Ten trials explicitly excluded those who had previously not responded to antidepressant treatment (Emslie 2002; Emslie 2006; Emslie 2009; Mirtazapine Trial 1 & 2; TADS 2004; Wagner Trial 1&2 (2003); Wagner 2004; Wagner 2006). The treatment period of the included trials was between 6 and 12 weeks.

Efficacy measures were collected throughout the treatment period and at completion of the trial. For four trials this was described as weekly (Almeida-Montes 2005; Emslie 1997; Emslie 2002; Keller 2001); for 11 trials this was near weekly (Berard 2006; Emslie 2006; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Emslie 2009; Mirtazapine Trial 1 & 2; Paroxetine Trial 1; Von Knorring 2006; Wagner 2004; Wagner 2006). Wagner Trial 1&2 (2003) stated that there were frequent follow-up visits but no further details were given. TADS 2004 described assessments at baseline, 6, 12, 18, 24, 30 and 36 weeks. There was no detail given for Simeon 1990.

Emslie 2009 specifically states that the high placebo response rate may be due to “extensive contact” (pg 728), which refers to this regular assessment.

Five trials (Emslie 1997; Emslie 2002; Keller 2001; TADS 2004; Wagner 2004) described a continuation phase. Emslie 1997 stated that after the eight weeks of acute treatment, treatment was not controlled and participants were followed up at 6 and 12 months. In a later report of Emslie 2002, two additional phases are described, one for non responders and one for relapse prevention, both of which were blinded. Keller 2001 stated that at the end of acute treatment (eight weeks), responders continued on blinded treatment (paroxetine, imipramine or placebo) for a further six months and non responders were tapered off medication and terminated from the trial. In TADS, after 12 weeks of acute treatment (after which the placebo group was unblinded and responders and partial responders given their choice of the three active intervention arms for 12 weeks), there was a six-week ‘consolidation’ phase for responders and partial responders, followed by an 18-week maintenance phase after which there was a 12-month naturalistic follow-up. Wagner 2004 stated that there was a 24-week open label extension trial.

With the exception of four trials (Almeida-Montes 2005; Emslie 1997; Emslie 2002; Emslie 2009), a flexible dosing scheme was used.
Clinician-rated depression symptom severity

Depression symptom severity was measured in a variety of ways, including:
1. The CDRS-R (Emslie 1997; Emslie 2002; Emslie 2006; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Emslie 2009; Mirtazapine Trial 1 & 2; Paroxetine Trial 1; TADS 2004; Wagner Trial 1 & 2 (2003); Wagner 2004; Wagner 2006).

The Children’s Depression Rating Scale (CDRS-R) (Poznanski 1984) was adapted for children and adolescents from the Hamilton Depression Rating Scale (HAM-D) and assesses 17 symptom areas. The first 14 items are rated on the basis of responses to interview questions by the child or an adult informant who knows the child well and are rated for the past two weeks and currently. The remaining three symptom areas (depressed facial affect, listless speech and hypoactivity) are rated by the clinician on the basis of the child’s non-verbal behaviour in the room. Each symptom is graded on a five or seven-point scale. For items 1 to 14 the highest ratings from the child, parent or other caretaker are taken as the item scores. The total score, or CDRS-R score, is the sum of all 17 item scores and has a range of 17 to 113. In samples studied in the development of the scale (Poznanski 1996) mean CDRS-R T scores (standardised scores) were 71, 58 and 53 for those with a depressive disorder (based on DSM-III criteria), other psychiatric disorder (outpatient) and no disorder respectively. This scale is used widely, has adequate internal reliability, good test-retest reliability, good to excellent inter-rater reliability and is sensitive to treatment effects (Myers 2002). We chose this measure for clinician-rated depressive symptom severity.

The Schedule for Affective Disorders and Schizophrenia for School Aged Children, Present Episode Version (K-SADS-P) (Chambers 1985) depression module has nine items on an ordinal scale, four of which consist of two to three sub-items. Each of the items or sub-items is rated from zero to either four or six with higher numbers corresponding to greater severity. The score range is 9 to 56. The various items are rated for the last two weeks in order to enable diagnosis according to DSM-IV criteria. It has reasonable reliability but is not often used to assess treatment outcome (Brooks 2001). Data based on the KSADS are reported in an additional table but not included in meta-analysis.
3. The HAM-D was used in the Simeon trial. Almeida-Montes 2005 used both the HAM-D and the Depression Self Rating Scale (DSRS) (the later was translated into Spanish).

The Hamilton Psychiatric Rating Scale for Depression (HAM-D) (Hamilton 1960) consists of 17 multiple choice questions each of which is numerically scored on a scale of zero to two or four. The score can range from 0 to 42 with a higher score indicating more severe depression. The various items refer to depressive disorder severity over the last week. Reliability is reported as excellent with trials suggesting sensitivity to treatment effects although further research is required (Myers 2002). There were no data for this outcome.
4. The MADRS was also used in Berard 2006 and Von Knorring 2006. The continuous data based on this measure was not meta-analysed. However, the dichotomised measure of this scale indicating response was meta-analysed (see below).

The Montgomery-Asberg Depression Rating Scale (MADRS) (Montgomery 1979) was also based on the HAM-D and is a clinician-rated scale that assesses depressive disorder symptoms in the last week or the last three days. This scale is less commonly used compared to other depression rating scales. It consists of 10 items covering apparent sadness, reported sadness, inner tension, reduced sleep, reduced appetite, concentration difficulties, lassitude, inability to feel, pessimistic thoughts and suicidal thoughts. Each of these items is scored between 0 and 6 based on severity. The possible range of scores is 0 to 60 with a higher score indicating more severe depression. This scale was specifically designed to assess the effect of treatment, but its psychometric properties have not been specifically examined in adolescents (Brooks 2001).

The CGI was also used in many trials, though not as a continuous measure of symptom severity outcome; rather it was often used to establish ‘response’. The Clinical Global Impression of Improvement (CGI-I) (Guy 1976) is a clinician-rated seven-point scale that assesses global improvement from baseline to the current state. The scale is:
1. very much improved
2. much improved
3. minimally improved
4. no change
5. minimally worse
6. much worse
7. very much worse

Response/ remission

Remission was measured in a variety of ways both across and within trials; few trials used diagnostic interviews to establish remission. More often it was defined by the trial authors as a level of improvement in depression symptoms on clinician-rated scales. The scale and the cut-point used to define this level of improvement varied between trials. Response was reported in all trials, however, again the scale used and the cut-point was variously defined between trials and usually, but not always, was of a smaller magnitude compared to remission. Therefore, as stated in the methods, for this version of the review, we have used remission in the first instance, but response if remission was not available. We have used LOCF data for the primary analysis of this outcome, and in one case this meant using response data rather than remission data (Wagner Trial 1 & 2 (2003)). In one trial OC data based on response was all that was available and we have used this (Almeida-Montes 2005). A large number of trials reported remission based on CDRS-R ≤ 28 (Emslie 1997; Emslie 2002; Emslie 2006 (for total population); Emslie 2009; TADS 2004). Two trials used this cut-point definition but labelled it ‘response’ (Wagner 2004; Wagner 2006).
Data from Von Knorring 2006 were based on what the trial authors called "remission", defined as a MADRS score of 12 or less. Data from Berard 2006 were based on what they called "response", defined as ≥ 50% reduction in baseline MADRS scores, and data from Keller 2001 were based on what they called "response", defined as HAM-D ≤ 8. Similarly, data from Almeida-Montes 2005 were based on what they called "response", defined as ≥ 50% reduction in DSRS and HAM-D score. Data from Emslie 2007 Trial 1 and Emslie 2007 Trial 2 were based on what they called "response" defined as ≥ 35% reduction in baseline CDRS-R scores. The data from Paroxetine Trial 1 were based on what they call "response" defined as a CGI score of 1 or 2 (much improved or very much improved). The paper publication of the sertraline trials (Wagner Trial 1 & 2 (2003)) did not include remission, however the MHRA reported these data using a definition of those who no longer met DSM-IV criteria for MDD; however because these MHRA data were only OC data, we have used response data defined as ≥ 40% reduction in baseline CDRS-R scores. Simeon 1990 and Mirtazapine Trial 1 & 2 did not provide any data for this outcome.

Self rated depression symptom severity

Self rated depression symptom severity was measured in four trials. Two trials (Berard 2006; Von Knorring 2006) used the Beck Depression Inventory (BDI) (Beck 1961); one trial (Emslie 1997) used the Children’s Depression Inventory (CDI) (Kovacs 1992) for child-aged participants and the BDI (Beck 1961) for adolescents and combined these into one score; and one trial (TADS 2004) used the Reynolds Adolescent Depression Scale (RADS) (Reynolds 1986). The BDI (Beck 1961) is the first and most widely used self rated tool to assess depression severity, consisting of 21 items of which there are four item choices related to how the respondent has felt in the last week. The range of possible scores is from 0 to 63, with higher scores indicating worse depression severity. The tool was developed for adults (Brooks 2001). The CDI (Kovacs 1992) was based on the BDI but specifically developed for children aged seven years and older and has been frequently used in younger adolescents. It has 27 items, with the first 18 very similar to the BDI, and there are three response options for each item. The range of possible scores is 0 to 54, with higher scores indicating greater severity (Brooks 2001). The RADS (Reynolds 1986) was developed for adolescents aged 13 to 18 years. It has 30 items with four response options per item to gauge the current severity of symptoms of depression with the range of possible scores from 30 to 120 (higher scores indicating greater severity) (Brooks 2001).

Functioning

Measures of function included the Children’s Global Assessment Scale (CGAS) (Almeida-Montes 2005; Berard 2006; Emslie 1997; Emslie 2009; TADS 2004; Wagner Trial 1; Wagner Trial 2; Wagner 2004; Wagner 2006), the Global Assessment of Functioning (GAF) (Emslie 2002; Emslie 2006; Von Knorring 2006) and the Autonomous Functioning Checklist (Keller 2001). One trial on paroxetine (Paroxetine Trial 1) and the trials of venlafaxine (Emslie 2007 Trial 1; Emslie 2007 Trial 2) and mirtazapine (Mirtazapine Trial 1 & 2) did not report data on functioning. The Children’s Global Assessment Scale (CGAS) (Shaffer 1985) measures a child’s current general functioning and is completed by the clinician. The range is from 1 to 100 with a score of 1 to 10 indicating a need for constant supervision and a 90 to 100 indicating superior functioning. The CGAS has adequate reliability and is sensitive to change (Myers 2002).

The Global Assessment of Functioning (GAF) (APA 2000) measure is a clinician-rated scale that assesses the patient’s current level of functioning. Scores range from 1 to 100 (90 indicates good functioning in all areas). There are few trials of its psychometric properties in child and adolescent populations; however, a recent review suggests it is likely to be reliable when used in research given the training and motivation of raters (Schorre 2004).

The Autonomous Functioning Checklist (AFC) (Sigafoos 1988) is completed by the parent, and assesses the child’s autonomy in performing daily activities. It consists of 78 questions grouped into four categories; 22 questions on self and family care; 20 questions on management; 16 questions on recreational activities; and 20 questions on social and vocational activities. The first three categories are rated on an ordinal scale ranging from 0 (“does not do”) to 4 (“does every time there is an opportunity”). While the last categories consist of “yes” (coded 1) and “no” (coded 0) questions. A total score and a sub-score for each of the four categories are calculated, with higher values indicating a greater degree of autonomy. There has been little psychometric investigation of this measure.

Suicide-related outcomes

Suicide-related outcomes were classified and reported in various ways in each of the trials. As described in the methods section, a post hoc decision was made in the first version of this review to use the data provided in an FDA report (Hammad 2004) in order to overcome inconsistent reporting of these outcomes across trial reports. The process of the FDA in establishing the rate of suicide-related outcomes for each trial was based on the following process. A group of 10 suicidology experts were assembled by Columbia University (led by Dr Kelly Posner). Suicide-related outcomes were defined after careful deliberation by this expert panel as including ‘definitive suicidal behaviour/ideation’ (pg 8, Hammad 2004) and where more than one event was recorded for an individual, the most severe event was used. The group of experts reviewed all of the suicide-related adverse events, all serious adverse events and all accidental injuries identified by the sponsors of SSRI trials. There
was some discrepancy between the sponsors’ classifications and the expert panel classification (with 22 new events added, and 26 old events removed). Overall there were no completed suicides in any of the trials. The report highlighted the important point that none of these trials had adequate power for safety analysis.

For this version of the review we have again extracted suicide-related outcomes from trials of depressive disorders from the FDA report (Hammad 2004) where they were available. Where the FDA did not include data for trials included in our review, we included data from the trial report (for TADS 2004 data were extracted from the Emslie 2006 report where it is stated that rates are based on a reanalysis by Columbia Group using the Columbia-Classification Algorithm for Suicidal Assessment); Emslie 2009 states their data are based on an increase in suicidal ideation and behaviour on the Modified Columbia Suicide Severity Rating Scale (MC-SSRS), a clinician-rated instrument; Wagner 2006 states that “potential suicide-related events were identified” and describes these in the results as adverse events, which is not equivalent to the data based on the Columbia Classification; for the mirtazapine trials (Mirtazapine Trial 1 & 2), the MHRA report gave a description of events stating there was one case of suicidal ideation in the mirtazapine group (both trials combined) and one case of self mutilation in the placebo group (both trials combined). The data for Paroxetine Trial 1 were suicidal ideation reported as an adverse event. The trial by Almeida-Montes 2005 did not provide data for this outcome.

We have also included, in this version of the review, suicidal ideation as a continuous outcome, which was measured by the Suicidal Ideation Questionnaire (Reynolds 1987) in both trials in which this instrument was used (Emslie 2009; TADS 2004).

Ongoing studies

Four included trials have been categorised as ongoing (Duloxetine NCT00849693; Duloxetine NCT00849901; Glod 2004; Solvay NCT00353028) (see Characteristics of ongoing studies), although the trials’ registration documentation suggests the duloxetine trials are completed, and the abstract by Glod 2004 was published some years ago. These are all individual patient parallel-group randomised trials. The two duloxetine and fluvoxamine (Solvay NCT00353028) trials are multicentre; it is unclear whether Glod 2004 is a single site or multicentre trial.

The duloxetine (SNRI) trials include two arms of duloxetine, one a flexible dose and one fixed, as well as a fluoxetine arm and a placebo arm all delivered for 10 weeks. These trials include children and adolescents treated in an outpatient setting with MDD according to DSM-IV (APA 2000) with additional inclusion criteria including a CDRS-R score of ≥ 45 and a CGI score of ≥ 4. The trials exclude participants with psychotic features or disorder, substance use or dependence, eating disorders, pervasive developmental disorder, obsessive compulsive disorder, a history of bipolar disorder, and those with first degree relatives with bipolar disorder. Those who had made a significant suicide attempt within one year of screening or were currently at risk of suicide in the opinion of the investigator were excluded. It is unclear how long the screening for inclusion takes or whether there is a placebo lead-in phase. There appears to be a continuation period for those on duloxetine with a 36-week follow-up. The CDRS-R is used as the measure of clinician-rated depression symptoms.

The Glod 2004 trial, published as a conference abstract, includes three arms: citalopram (SSRI), bupropion (NDRI) and placebo, delivered for eight weeks. It is unclear whether flexible or fixed dosing is used. The trials include adolescents treated in an outpatient setting with MDD according to DSM-IV (APA 2000) with no additional inclusion criteria stated. It is unclear what the screening procedure for trial entry was, or whether there was a placebo lead-in. In addition, it was unclear what psychiatric conditions were excluded or whether those with suicide risk were excluded. The conference abstract did provide some information on the first 18 young people randomised into the trial. Their mean age was 15.5; six were males and 12 females and their baseline level of depression symptom severity was 20.3 on the HAM-D. Few other details were provided.

The Solvay NCT00353028 trial undertaken in Japan includes two arms: fluvoxamine maleate (flexible dose) (SSRI) and placebo delivered for 38 weeks. Flexible dosing was used (25 mg to 150 mg). The trials include children and adolescents with MDD diagnosed using the Japanese Version of the Structured Interview Guide for the Hamilton Depression (JSIGH-D) (minimum total score of 18 on the JSIGH-D). An additional inclusion criteria was weight within the standard weight. Exclusion criteria were a predominant psychiatric diagnosis of schizophrenia, or previously been treated with fluvoxamine maleate.

Excluded studies

In the original review, there were eight excluded studies. These were excluded due to the intervention not being an SSRI; one trial was a head-to-head trial of antidepressants that did not include a placebo; one trial was a case-control trial and one trial included participants with bipolar disorder not depressive disorder.

Of these, the two trials on venlafaxine and the two trials on mirtazapine are now included in the update due to the inclusion criteria changing to include SSRIs as well as newer generation antidepressants.

In this version of the review, based on the updated search, seven new studies were excluded. The primary reasons for exclusion included the following: two did not have a pure newer generation antidepressant or placebo treatment arm; two focused on co-morbid substance use; one used an antidepressant that did not meet the inclusion criteria for antidepressants considered in this review; and two were not randomised trials.

Risk of bias in included studies

Newer generation antidepressants for depressive disorders in children and adolescents (Review)
See Figure 2 for the 'Risk of bias' graph that shows the proportion of studies with each of the judgements and Figure 3 for the 'Risk of bias' summary showing all the judgements in a cross-tabulation by trial.

**Figure 2.** 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

**Allocation**

There were no full reports of allocation concealment in any of the included trials.

**Blinding**

All trials were described as being "double-blind" or of having the relevant treatment arms double-blind (TADS). In two trials (Emslie 1997; Emslie 2002) the description of blinding indicates that the antidepressant and placebo medications were identical. There is little description of the blinding in 10 trials, so that it is unclear what "double-blind" refers to (Emslie 2007 Trial 1; Emslie 2007 Trial 2; Emslie 2009; Mirtazapine Trial 1 & 2; Paroxetine Trial 1; Simeon 1990; Von Knorring 2006; Wagner 2004; Wagner 2006). Almeida-Montes 2005 and TADS 2004 state that there were independent evaluators who were also "blind". Emslie 1997 mentions that the pharmacy staff were blind. There were no reports on the success of blinding in any of the trials, and the possibility of clinicians or patients guessing the nature of the intervention from side effects was not discussed. Given outcomes were based on ratings by participants and clinicians, this could be an important omission, although the updated CONSORT guidelines highlight that asking participants or healthcare providers what intervention they received as a test of blinding at the end of the trial is confounded because usually by this stage they know what intervention they received (Moher 2010).

**Incomplete outcome data**

One trial was discontinued early (Simeon 1990) and it is unclear whether this is also the case for Glod 2004. One trial of paroxetine was aiming to recruit 65 participants in each of the treatment and placebo arms, however, it appeared to cease recruitment with less than half this number recruited to each group. The attrition rate for the 18 trials varied between 11% and 82% in the control groups and 14% and 58% in the intervention groups (see Table 4). The disparity in attrition between treatment arms was of particular concern in the trials of fluoxetine (Table 4). All authors stated that intention-to-treat analyses (ITT) had been undertaken. However, a full application of the intention-to-treat principle is only possible when complete outcome data are available for all randomised participants (Hollis 1999). Only two trials (Emslie 1997; TADS 2004) appear to include all patients randomised in their analyses (the Paroxetine Trial 1 appears to include all randomised patients only in their primary analysis). In the other trials, analyses are carried out on fewer patients than the number randomised. For the majority of trials, only those who received at least one dose of medication or placebo, or had at least one post baseline efficacy or safety evaluation were included in the analyses.

**Selective reporting**

There is some evidence of reporting bias in some of the trials, though this is difficult to assess in most trials, since it was not possible to obtain the trial protocol. The trial report by Emslie 2002 emphasises CDRS-R scores and remission rates rather than response rate, even although response rate was specified as the primary outcome in the methods section. Additionally, the cut-off used for remission rate differed from that stated in the methods section. Emslie 1997 reports outcomes at five weeks rather than at the completion of the trial. In a letter to the editor, Keller 2001 was criticised for changing the definition of response post data analysis to a cut-off that showed treatment effectiveness (Jureidini 2003). In response, Keller 2001 changed their claim of finding a significant effect to stating that the findings showed a strong signal for efficacy (Jureidini 2004; Keller 2003). In many trials response/remission is defined, measured and reported in many different ways within the trial, without it being clear what the primary outcome is, e.g. Emslie 2009 reports two different results for response using two different definitions. The report by Wagner Trial 1&2 (2003) and Emslie 2007 combines the results of two trials and in most cases reports the overall outcomes. Wagner 2006 emphasises post hoc subgroup analyses. The outcomes for TADS 2004 have been reported in multiple publications with the reporting of outcome results that are not consistent across papers. For trials where results are only reported in the MHRA report, there are few data reported (e.g. Mirtzapine Trial 1 & 2). For one trial of paroxetine there is no publication except a brief pharmaceutical company trial report. In many cases, trials appear not to have measured or reported the outcomes specified as outcomes for this review, or have reported data in a way that means they cannot be used in meta-analysis, so that there are data missing from the meta-analyses. It appears that two of the included trials have been stopped early Simeon 1990 and Glod 2004. There were no data reported from Simeon on the 40 participants who were included. Glod 2004 reports data on depression symptom severity (but not by group) on the first 18 participants and we have been unable to find publication of the full trial, despite our efforts to contact the author and pharmaceutical company.

**Reporting bias**

The funnel plots for the outcomes remission (Figure 4) and suicide-related behaviour (Figure 5) were not suggestive of small-study effects. In addition, the contour-enhanced funnel plots (Figure 6; Figure 7) did not indicate that statistically significant results were more likely to be reported (publication bias). Harbord’s test for small-study effects was non-significant for both outcomes (remission P value = 0.364; suicide-related behaviour P = 0.275).
Figure 4. Funnel plot of comparison: 1 Newer generation antidepressant versus placebo (by medication), outcome: 1.2 Remission or response (as defined in trial) LOCF only.
Figure 5. Funnel plot of comparison: 1 Newer generation antidepressant versus placebo (by medication), outcome: 1.6 Suicide-related outcome.
Figure 6. Contour-enhanced funnel plot for the outcome remission or response (mix of OC and LOCF). The dashed vertical line represents the pooled random-effects estimate.
Other potential sources of bias

Funding
Most trials, with the exception of Emslie 1997, were pharmaceutically funded. The TADS 2004 trial was funded by an NIMH contract but had an "unrestricted educational grant from Eli Lilly" (pg 531 of the 2003 publication).

Compliance
Eleven trial reports did not describe any method for assessing compliance with intervention. Three trials (all of paroxetine) attempted to assess compliance by pill count (Berard 2006; Emslie 2006; Keller 2001) and six trials assessed plasma blood levels of the investigative trial medication (Emslie 1997; Mirtazapine Trial 1; Mirtazapine Trial 2; Paroxetine Trial 1; Simeon 1990; Von Knorring 2006).

Additional therapy
Some trials gave details about additional support or psychotherapy provided to participants in the medication and placebo arms of trials. Psychotherapy was not permitted in Wagner 2004; Wagner 2006 and the mirtazapine trials (Mirtazapine Trial 1 & 2), although in the mirtazapine trials 'supportive care' was permitted, with no detail about how many received this. Non directive supportive therapy was permitted in Berard 2006 but again no details are provided about how many young people received this. Supportive case management (including CBT and interpersonal therapy interventions) was provided to all participants in Keller 2001. Therapy was permitted in the sertraline trials Wagner Trial 1&2 (2003) and it is unclear how many received this; Von Knorring 2006 reports that psychotherapy was permitted and three-quarters of participants received it. In TADS 2004 each participant received six 20 to 30-minute medication visits spread across 12 weeks of treatment (pg 809) during which their pharmacothe-
apy for MDD. For the remainder of the trials there is no detail given about the provision of support or therapy (Almeida-Montes 2005; Emslie 1997; Emslie 2002; Emslie 2006; Emslie 2007 Trial 1; Emslie 2007 Trial 2; Emslie 2009; Simeon 1990).

Effects of interventions

See: Summary of findings for the main comparison Second generation antidepressant versus placebo (by medication) for depressive disorders in children and adolescents

A. Comparison 1: Newer generation antidepressants versus placebo

Primary outcomes

1. Depressive disorder according to DSM or ICD criteria and established by a clinician conducting a structured or semi-structured diagnostic interview

No data were provided for this outcome.

2. Suicide completion

No data were provided for this outcome.

Secondary outcomes

1. Efficacy outcomes

1.1 Depression symptom severity (clinician-rated)

Compared with placebo, there was a small, statistically significant reduction in depression symptoms on the Children’s Depression Rating Scale (CDRS-R) for those taking an antidepressant (14 trials; N = 2490; mean difference (MD) -3.51; 95% confidence interval (CI) -4.55 to -2.47) (Analysis 1.1). The majority of estimates were in the same direction, favouring antidepressants, with little heterogeneity (Chi² = 13.22; df = 13 (P = 0.43); I² = 2% (95% CI 0% to 48%)). There was no evidence that the individual drug class modified the effect of the newer generation antidepressants (Chi² = 8.23; df = 6, P = 0.22) (Figure 8). Three trials measured clinician-rated symptoms using the Schedule for Affective Disorders and Schizophrenia for School Aged Children (K-SADS); two of which tested paroxetine (Berard 2006; Keller 2001) and one which tested citalopram (Von Knorring 2006). Data have been extracted for this measure and are available in Table 1.
Figure 8. Forest plot of comparison: 1. Second generation antidepressant versus placebo (by medication), outcome: 1.1 Depressive symptom severity (CDRS-R).

</table>
We judged all trials to be at a high risk of bias, precluding a sensitivity analysis investigating how trials at a high risk of bias modify the pooled treatment effect. The pooled treatment effect was not modified in a clinically important way with removal of the antidepressant classes selective norepinephrine reuptake inhibitors (SNRI) (venlafaxine) and tetracyclic antidepressants (TeCA) (mirtazapine) (sensitivity analysis pooled treatment effect: MD -3.73; 95% CI -5.09 to -2.36).

1.2 and 1.3 Remission or response

Compared with placebo, there was a statistically significant increase in the percentage of those who remitted/responded when taking an antidepressant (16 trials; N = 2924; risk ratio (RR) 1.18; 95% CI 1.08 to 1.28) (Analysis 1.2). There was generally consistency in the direction of effect across the trials, favouring antidepressant (Chi² = 15.87, df = 14 (P = 0.32); I² = 3% (95% CI 0 to 53)). There was no evidence that individual drug class modified the effect of the intervention, compared with placebo (Chi² = 1.79; df = 5; P = 0.88). The two trials testing mirtazapine did not provide data on response or remission.

We undertook sensitivity analysis to test the impact of using observed case (OC) data rather than last observation carried forward (LOCF) data. We had OC data for the trials of sertraline (Wagner Trial 1&2 (2003)), the four trials of paroxetine (Berard 2006; Emslie 2006; Keller 2001; Paroxetine Trial 1) and one trial of citalopram (Von Knorring 2006). Including OC data did not modify the pooled effect in an important way (RR 1.17; 95% CI 1.09 to 1.25) and there was no evidence of heterogeneity (Chi² = 14.12, df = 15 (P = 0.52); I² = 0% (95% CI 0 to 45)) (Analysis 1.3).

We judged all trials to be at a high risk of bias, precluding a sensitivity analysis investigating how trials at a high risk of bias modify the pooled treatment effect. The pooled treatment effect was not modified in a clinically important way with the removal of the antidepressant class SNRI (venlafaxine) (sensitivity analysis pooled treatment effect: RR 1.19; 95% CI 1.07 to 1.32).

1.4 Depression symptom severity (self rated)

For self report depression scores, only five trials measured or reported this. One of these only reported median scores (Emslie 2006) and another did not report any measure of variance (Von Knorring 2006); however, we included Von Knorring 2006 assuming the baseline standard deviations from Berard 2006 as the follow-up standard deviations of Von Knorring 2006. Three trials used the Beck Depression Inventory (BDI)/Childrrens Depression Inventory (CDI) (Berard 2006; Emslie 1997; Von Knorring 2006). There was no evidence that self report depression scores were reduced for those taking an antidepressant (paroxetine and fluoxetine respectively) compared with placebo (N = 564; MD -0.53; 95% CI -2.37 to 1.31) (Analysis 1.4). There was little variability and consistency in the direction of treatment effects between trials; however, with few trials, the confidence interval for I² was wide (Chi² = 0.14, df = 2 (P = 0.93), I² = 0% (95% CI 0% to 73%)).

TADS 2004 reported data based on Reynolds Adolescent Depression Scale (RADS) final scores, with results available in Table 2.

1.5 Functioning

Nine trials measured functioning using the Children’s Global Assessment Scale (CGAS) with only one (Almeida-Montes 2005) that did not provide usable data. There was evidence that antidepressants improved functioning compared with placebo (N = 1593; MD 2.20; 95% CI 0.90 to 3.49) (Analysis 1.5). There was consistency in the direction of treatment effects and little between-trial variability (Chi² = 0.91, df = 6 (P = 0.99); I² = 0% (95% CI 0% to 58%)). There was no evidence that the effect of newer generation antidepressants was modified by individual drug class (Chi² = 0.81; df = 4; P = 0.94). Three trials used Global Assessment of Functioning (GAF) to measure functioning with only two providing data (Emslie 2006 (paroxetine) and Emslie 2002 (fluoxetine); Von Knorring 2006 (citalopram) did not provide usable data. One trial (Keller 2001 (paroxetine) used the Autonomous Functioning Checklist. We have extracted data for these other measures and they are available in Table 3. The two trials of venlafaxine and the two trials of mirtazapine did not provide evidence that this outcome was measured.

2. Suicide-related outcomes (suicide-related behaviour and suicidal ideation)

Seventeen trials had data on suicide-related outcomes. There was evidence of an increased risk in suicide-related outcomes for those receiving antidepressants compared with placebo (17 trials; N = 3229; RR 1.58; 95% CI 1.02 to 2.45) (Analysis 1.6). There was little heterogeneity and generally consistency in the direction of effects (Chi² = 16.62, df = 13 (P = 0.22); I² = 22% (95% CI 0% to 58%)). There was no evidence that the effect of new generation antidepressants on suicide-related outcomes was modified by drug class (Chi² = 8.06; df = 6; P = 0.23).

We judged all trials to be at a high risk of bias, precluding a sensitivity analysis investigating how trials at a high risk of bias modify the pooled treatment effect. The pooled treatment effect was not modified in a clinically important way with the removal of the antidepressant class SNRI (venlafaxine) (sensitivity analysis pooled treatment effect: RR 1.46; 95% CI 1.20 to 1.75) (Analysis 1.7). There was little variability and consistency in the direction of treatment effects between trials; however, with few trials, the confidence interval for I² was wide (Chi² = 4.24, df = 11 (P = 0.86), I² = 20% (95% CI 0% to 73%)).
ideation on the Suicidal Ideation Questionnaire self-report measure and showed no statistically significant evidence of effect on suicidal ideation for those taking an antidepressant compared with placebo (N = 532; MD 0.70; 95% CI -1.50 to 2.91) (Analysis 1.7). From the Medicines and Healthcare Products Regulatory Agency (MHRA) report, it was stated that Wagner 2004 (child and adolescent) showed that citalopram was superior to placebo in reducing suicidal ideation based on item 13 of the CDRS-R; however, the report did not provide an estimate of the effect or measure of precision. Likewise, the MHRA report stated that the trial by Von Knorring 2006 (adolescents only) showed that those taking citalopram had a slightly greater improvement in suicidal ideation than placebo, based on item nine of the K-SADS-P. However, an estimate of intervention effect (or precision) was not provided. No other trials reported a measure suicidal ideation.

3. Adverse outcomes

Eleven trials reported the number of children, adolescents or both who experienced any adverse event. These data were not available from the trials of sertraline, venlafaxine or mirtazapine or for two of the fluoxetine trials (Almeida-Montes 2005; Emslie 1997). There was an increased risk of adverse events in those taking antidepressants compared with placebo (11 trials, N = 2136; RR 1.11; 95% CI 1.05 to 1.17) (Analysis 1.8). There was little heterogeneity and generally consistency in the direction of effects (Chi² = 9.42 df = 9 (P = 0.40); I² = 4% (95% CI 0% to 55%)). There was no evidence that the effect of new generation antidepressants on suicide-related outcomes was modified by drug class (Chi² = 3.31; df = 3; P = 0.35).

Side effects were reported differently in each trial, and a summary of the adverse events reported is available in Table 4.

4. Completion of trial protocol

The rates of participants completing the trial did not differ between groups (18 trials; N = 3290; RR 0.99; 95% CI 0.94 to 1.05) (Analysis 1.9). However, there was some evidence of moderate heterogeneity in the relative rates of completion (Chi² = 25.82, df = 15 (P = 0.04); I² = 42% (95% CI 0% to 67%)). Although not statistically significant (Chi² = 9.66; df = 6; P = 0.14), there was moderate variability in relative rates of completion among the individual drug class (I² = 37.9% (95% CI 0% to 74%)). Table 5 contains the full attrition rates for all trials.

B. Comparison 1: Subgroup analyses: new generation antidepressants versus placebo by individual drug

1. Paroxetine

There were four trials on paroxetine that provided some outcome data.

Depression symptom severity (clinician-rated)

Meta-analysis of two trials reporting CDRS-R scores showed a non statistically significant reduction in depression symptom severity scores for those taking paroxetine compared with those taking placebo (MD -1.18; 95% CI -6.29 to 3.92) (Figure 8). Data based on the K-SADS are available in Table 1.

Remission or response

There was no statistically significant increase in the percentage of those who met the criteria for response/remission when taking paroxetine compared with placebo (four trials; N = 704; RR 1.12; 95% CI 0.90 to 1.38) (on the criteria of ‘response’ for Berard 2006, Keller 2001 and Paroxetine Trial 1 and remission for Emslie 2006). The response rate in the treatment groups in the three trials varied between 52% and 63%, and the response rates in the placebo groups varied between 41% and 58%; the remission rate in Emslie 2006 was 23% in the treatment group and 28% in the placebo group. We undertook sensitivity analysis to test the impact of using OC data rather than LOCF data. Including OC data did not modify the pooled effect in an important way (four trials; N = 522; RR 1.11; 95% CI 0.98 to 1.27) (on the criteria of ‘response’ for Berard 2006, Keller 2001 and Paroxetine Trial 1 and remission for Emslie 2006). The response rate in the treatment groups in the three trials varied between 56% and 81% and the response rates in the placebo groups varied between 46% and 71%; the remission rates in Emslie 2006 were 34% in the treatment group and 36% in the placebo group. It is clear that high attrition combined with the imputation strategy in the component trials impacts on the absolute rates.

Depression symptom severity (self-rated)

One trial (Berard 2006) measured self-report depression symptom severity and showed no statistically significant difference between groups (MD -0.43; 95% CI -2.91 to 2.05).

Functioning

There was no evidence that paroxetine improved functioning compared with placebo on the Children’s Global Assessment Scale (CGAS) in Berard 2006 (MD 1.60; 95% CI -2.48 to 5.68). Data based on other measures used are presented in Table 3.
Suicide-related outcomes
While there was evidence of an increased risk in suicide-related outcomes for those receiving paroxetine compared with placebo (Berard 2006; Emslie 2006; Keller 2001), the confidence interval was wide and did not exclude the possibility of no difference in the rates of suicide-related outcomes between groups (RR 1.57; 95% CI 0.46 to 5.31).

Adverse outcomes
There was no statistically significant increase in risk of adverse events in those taking paroxetine compared with placebo (RR 1.11; 95% CI 0.98 to 1.25). However, there was some evidence of moderate heterogeneity (Chi² = 4.69, df = 3 (P = 0.20); I² = 36% (95% CI 0% to 79%)) with three trials (Berard 2006; Emslie 2006; Keller 2001) demonstrating that adverse events were more common for those receiving paroxetine, but one demonstrating the opposite effect (Paroxetine Trial 1). Headaches were common side effects in both groups, as were nausea and dizziness. Somnolence, insomnia and emotional lability were also noted. Side effects were reported differently in each trial, and a summary of the adverse events reported is in Table 4.

Completion of trial protocol
The rates of participants completing the trial did not differ between the paroxetine and placebo groups (RR 0.94; 95% CI 0.86 to 1.02).

2. Fluoxetine
Four of five trials investigating the effectiveness of fluoxetine provided some outcome data.

Depression symptom severity (self rated)
There was no evidence that self report depression scores were reduced for those taking fluoxetine compared with placebo (MD -1.30; 95% CI -5.87 to 3.27) on the CDI/BDI in one trial (Emmslie 1997). TADS 2004 reported data based on RADS final scores with results available in Table 2.

Functioning
Fluoxetine improved functioning when measured by the C-GAS from two trials (Emmslie 1997; TADS 2004) (MD 3.08; 95% CI 0.14 to 6.02). Emslie 2002 measured functioning using the GAF and data based on this measure are available in Table 3.

Suicide-related outcomes
While there was evidence of an increased risk in suicide-related outcomes for those receiving fluoxetine compared with placebo, the difference between groups was not statistically significant (RR 1.77; 95% CI 0.85 to 3.69). There was no difference between groups in suicidal ideation scores post intervention in the one trial that measured this (TADS 2004).

Adverse outcomes
Data on adverse outcomes could not be extracted for Almeida-Montes 2005 or Emslie 1997. Based on two trials there was an increased risk of adverse events in those taking fluoxetine compared with placebo (RR 1.19; 95% CI 1.05 to 1.35). Details about particular adverse events were only reported for TADS, in which the following adverse events were reported: headaches, diarrhoea, somnolence, insomnia, emotional lability, and mania or hypomania. Headache was most commonly reported with 12% and 9% of those in the fluoxetine and placebo groups experiencing these respectively. All other adverse events were reported in less than 3% of the participants, with similar rates observed in both groups. Details can be found in Table 4.

Completion of trial protocol
Based on four trials, the rates of participants completing the trial did not differ between those taking fluoxetine compared with placebo (RR 1.16; 95% CI 0.97 to 1.40).

3. Sertraline
There were two trials of sertraline. These trials were combined and treated as a single trial in the publication (Wagner Trial 1). The trial author states that “data were pooled in a prospectively defined combined analysis” (Wagner Trial 1, pg 1035). The author states that this pooling was planned a priori. The MHRA report,
however, reported results for the two trials separately. In total, 376 young people were randomised into the two trials.

Depression symptom severity (clinician-rated)
Compared with placebo, there was a statistically significant reduction in depression symptoms on the CDRS-R for those receiving sertraline (MD -3.52; 95% CI -6.64 to -0.40) (Figure 8).

Remission or response
Compared with placebo, there was no statistically significant increase in the percentage of those who responded when taking sertraline (two trials; N = 364; RR 1.17; 95% CI 1.00 to 1.36). The percentage of young people who met the criteria for response in the sertraline groups (two trials combined) was 69% and in the placebo groups was 59%.

We undertook sensitivity analysis to test the impact of using OC data rather than LOCF data. Including OC data did not modify the effect in an important way (RR 1.18; 95% CI 1.01 to 1.38). The percentage of young people who met the criteria for response in the sertraline groups (two trials combined) was 69% and in the placebo groups was 59%.

Depression symptom severity (self rated)
Self rated depressive symptom severity was not measured in these trials.

Functioning
Functioning was measured using the CGAS scale in both trials and there was no evidence that antidepressants improved functioning for those taking sertraline compared with placebo (MD 1.31; 95% CI -1.61 to 4.23).

Suicide-related outcomes
While there was evidence of an increased risk in suicide-related outcomes for those receiving sertraline compared with placebo, the difference between groups was not statistically significant and the confidence interval was wide (RR 2.97; 95% CI 0.61 to 14.52).

Adverse outcomes
Data were not provided for the number of overall adverse events in each group. Nausea was commonly reported in both groups. Adverse effects that were reported relatively frequently included diarrhoea, vomiting and insomnia. Emotional lability but not mania/hypomania was reported (see Table 4).

Completion of trial protocol
The rates of participants completing the trial did not differ between groups (RR 0.91; 95% CI 0.82 to 1.01).

4. Citalopram
There were two trials of citalopram.

Depression symptom severity (clinician-rated)
There was no statistically significant difference in the reduction of depression symptom severity scores (CDRS-R) for those taking citalopram compared with placebo based on one study (Wagner 2004) (MD -2.90; 95% CI -7.77 to 1.97) (Figure 8). Data from Von Knorring 2006 using the K-SADS measure are available in (Table 1).

Remission or response
Compared with placebo, there was a non statistically significant increase in the percentage of those who met the criteria for remission when taking citalopram (two trials; N = 407; RR 1.16; 95% CI 0.71 to 1.89). In the two trials of citalopram (Von Knorring 2006; Wagner 2004), the percentage of participants remitting in the citalopram groups varied between 33% and 36% and in the placebo groups between 24% and 36%.

We undertook sensitivity analysis to test the impact of using OC data rather than LOCF data. Including OC data from Von Knorring 2006 did not modify the pooled effect in an important way (RR 1.17; 95% CI 0.74 to 1.85). The response rate based on OC for those on citalopram was 51% (compared to 33% based on LOCF data) and 53% (compared to 36% based on LOCF data) for those in the placebo group.

Depression symptom severity (self rated)
One trial (Von Knorring 2006) provided data on self reported depression symptom severity and showed no difference between groups (MD -0.28; 95% CI -3.72 to 3.16).

Functioning
Data on improvement in functioning (CGAS) were available from one trial. There was no evidence that citalopram improved functioning compared with placebo (MD 2.50; 95% CI -1.52 to 6.52).

Suicide-related outcomes
While there was evidence of an increased risk in suicide-related outcomes for those receiving citalopram compared with placebo, the difference between groups was not statistically significant (RR 1.53; 95% CI 0.55 to 4.27).
Adverse outcomes
There was no increased risk of adverse events in those taking citalopram compared with placebo (two trials; RR 1.13; 95% CI 1.00 to 1.29). Headache was a commonly reported adverse outcome, as well as nausea, diarrhoea and insomnia. Dizziness and respiratory adverse events were also recorded. Emotional lability and mania/hypomania were not reported (see Table 4).

Completion of trial protocol
The rates of participants completing the trial did not differ between groups (two trials; RR 1.03; 95% CI 0.91 to 1.16).

5. Escitalopram
There were two trials of escitalopram.

Depression symptom severity (clinician-rated)
Compared with placebo, there was a statistically significant reduction in depression symptoms on the CDRS-R for those taking an escitalopram (two trials; MD -2.67; 95% CI -4.85 to -0.48) (Figure 8).

Remission or response
There was no statistically significant increase in the percentage of those who met the criteria for remission when taking escitalopram compared with placebo (RR 1.19; 95% CI 0.97 to 1.45). In the two trials, the percentage of participants who met the criteria for remission was 42% in the escitalopram group and 36% in the placebo group in Emslie 2009 and 46% in the escitalopram group and 38% in the placebo group in Wagner 2006.

Depression symptom severity (self rated)
There were no data on self reported depression symptom severity.

Functioning
Data on improvement in functioning (CGAS) were available from both trials. There was evidence that escitalopram improved functioning compared with placebo (MD 2.28; 95% CI 0.23 to 4.32).

Suicide-related outcomes
There was evidence of reduced risk in suicide-related outcomes for those receiving escitalopram compared with placebo, however the confidence interval did not exclude the possibility of no difference in risks between groups (RR 0.91; 95% CI 0.47 to 1.76).

Adverse outcomes
There was no difference in the risk of adverse events in those taking escitalopram compared with placebo (RR 1.03; 95% CI 0.94 to 1.14). In the Wagner 2006 trial, headache was a commonly reported adverse outcome, as well as nausea, diarrhoea and insomnia. Dizziness and respiratory adverse events were also recorded. Emotional lability and mania/hypomania were not reported. In the Emslie 2009 trial, abdominal pain, nausea, vomiting and dizziness were reported more often in the escitalopram group; headache, abdominal pain, diarrhoea, pharyngitis and rhinitis were reported in both groups (Table 4).

Completion of trial protocol
The rates of participants completing the trial did not differ between groups (RR 0.93; 95% CI 0.86 to 1.01).

6. Venlafaxine
There were two trials of venlafaxine.

Depression symptom severity (clinician-rated)
There was no statistically significant reduction of depression symptom severity scores (CDRS-R) for those taking venlafaxine compared with placebo in two trials (MD -1.90; 95% CI -4.79 to 0.99) (Figure 8).

Remission or response
There was no statistically significant increase in the percentage of those who met the criteria for response when taking venlafaxine compared with placebo in two trials (RR 1.16; 95% CI 1.00 to 1.35). In Emslie 2007 Trial 1, the percentage of participants responding in the venlafaxine group was 63% compared with 51% in the placebo group and in Emslie 2007 Trial 2 the percentage of participants responding in the venlafaxine group was 76% compared with 67% in the placebo group.

Depression symptom severity (self rated)
There were no data on self reported depression symptom severity.

Functioning
There were no data on functioning.

Suicide-related outcomes
There was evidence of an increased risk of suicide-related outcomes for those receiving venlafaxine compared with placebo, although there were few suicide-related events and the resulting confidence interval was very wide (one trial; RR 12.93; 95% CI 1.71 to 97.82).
Adverse outcomes
There were no data on the number of overall adverse events experienced by young people in these trials. Data on individual adverse events highlighted that abdominal pain and dizziness were reported more often in the treatment than the placebo group (see Table 4).

Completion of trial protocol
The rates of participants completing the trial did not differ between groups (RR 1.05; 95% CI 0.93 to 1.19).

7. Mirtazapine
There were two trials of mirtazapine.

Depression symptom severity (clinician-rated)
There was no statistically significant reduction of depression symptom severity scores (CDRS-R) for those taking mirtazapine compared with placebo (MD -2.79; 95% CI -6.42 to 0.83) (Figure 8).

Remission or response
No data on rates of remission or response were reported.

Depression symptom severity (self rated)
No data on self reported depression symptom severity were reported.

Functioning
No data on functioning were reported.

Suicide-related outcomes
There was evidence of reduced risk of suicide-related outcomes for those receiving mirtazapine compared with placebo, however the confidence interval did not exclude the possibility of no difference in risks between groups (RR 0.50; 95% CI 0.03 to 7.90).

Adverse outcomes
There were no data on the number of overall adverse events experienced by young people in these trials. Reports highlight a side effect profile for this medication that includes significant metabolic side effects including greater weight gain, increased appetite and hypertriglyceridaemia. The mirtazapine group also experienced greater somnolence, headaches, fatigue and urticaria (hives).

C. Comparison I: Subgroup analyses: newer generation antidepressants versus placebo by age (children versus adolescents)

Depression symptom severity (clinician-rated)
There was no evidence that age modified the effect of the newer generation antidepressants for any outcome including the following.
- Depression symptom severity (Chi^2 = 0.44; df = 1, P = 0.51).
- Remission or response (Chi^2 = 1.54; df = 1, P = 0.21).
- Functioning (Chi^2 = 0.11; df = 1, P = 0.74).
- Suicide-related outcomes (Chi^2 = 0.31; df = 1, P = 0.58).
- Adverse outcomes (Chi^2 = 0.02; df = 1, P = 0.89).

1. Children

Depression symptom severity (clinician-rated)
Compared with placebo, there was a statistically significant reduction in depression symptoms on the CDRS-R for children taking an antidepressant (eight trials; MD -3.18; 95% CI -5.95 to -0.41) (Analysis 2.1).

Remission or response
Only two trials provided data on children separately (Emslie 2002; Emslie 2006). There was no statistically significant increase in the percentage of those who responded/remitted when receiving an antidepressant compared with placebo (RR 1.71; 95% CI 0.90 to 3.25) (Analysis 2.2).

Depression symptom severity (self rated)
Data were not available separately for children in the one trial (Emslie 1997) which reported self rated depression symptom severity that included this age group.

Functioning
Compared with placebo, there was no evidence that antidepressants improved functioning in children in two trials (Emslie 1997; Wagner 2006) (MD 1.41; 95% CI -6.74 to 9.57) (Analysis 2.4). Functioning data were not available separately for children for the trials of sertraline (Wagner Trial 1&2 (2003)) or the citalopram trial (Wagner 2004).
Suicide-related outcomes

While there was evidence of an increased risk in suicide-related outcomes for children receiving an antidepressant compared with placebo, the difference between groups was not statistically significant (RR 2.07; 95% CI 0.67 to 6.35) (Analysis 2.5).

Adverse outcomes

Only one trial of children and adolescents (Emslie 2006) provided data on adverse outcomes separately for children and there was no evidence of an increased risk of adverse events in children taking antidepressants compared with placebo (RR 1.09; 95% CI 0.82 to 1.44) (Analysis 2.6).

Completion of trial protocol

Data on trial completion by age group were not available.

2. Adolescents

Depression symptom severity (clinician-rated)

Compared with placebo, there was a statistically significant reduction in depression symptoms on the CDRS-R for adolescents taking an antidepressant (10 trials; MD -4.21; 95% CI -5.50 to -2.92) (Analysis 2.1).

Remission or response

Compared with placebo, there was a statistically significant increase in the percentage of adolescents who met the criteria for remission or response on an antidepressant (seven trials; RR 1.13; 95% CI 1.02 to 1.26) (Analysis 2.2).

Depression symptom severity (self-rated)

Data were not available separately for adolescents in one trial (Emslie 1997) reporting self-rated depression symptom severity. The other trial, which included only adolescents, measured symptom severity using the BDI and observed no evidence that scores were reduced for those taking an antidepressant compared with placebo (MD -0.43; 95% CI -3.09 to 2.23) (Analysis 2.3).

Functioning

In the five trials of adolescents, or trials that provided data on functioning using the CGAS separately for adolescents, there was evidence that antidepressants improved functioning compared with placebo (MD 2.82; 95% CI 1.17 to 4.47) (Analysis 2.4). Functioning data were not available separately for adolescents for the trials of sertraline (Wagner Trial 1&2 (2003)) or for the citalopram trial (Wagner 2004).

Suicide-related outcomes

While there was evidence of an increased risk of suicide-related outcomes for adolescents receiving an antidepressant compared with placebo, the difference between groups was not statistically significant, although the effects encompassed by the confidence interval were generally suggestive of an increased risk (RR 1.47; 95% CI 0.99 to 2.19) (Analysis 2.5).

Adverse outcomes

There were six trials of adolescents or trials that reported data separately for adolescents and combined. There was an increased risk of adverse events in those taking antidepressants compared with placebo (RR 1.11; 95% CI 1.04 to 1.19) (Analysis 2.6).

Completion of trial protocol

Data on trial completion by age group were not available.

DISCUSSION

Summary of main results

We cannot make any comment on the comparative efficacy of individual antidepressant compounds. However, based on our meta-analyses, there was no evidence that the magnitude of intervention effects (compared with placebo) was modified by individual drug class. Pooled results showed some evidence that depression symptoms were reduced and that remission/response rates were higher in those taking a newer generation antidepressant compared to placebo. The clinical importance of these effects is unclear. Overall, the reduction in depression symptoms was relatively small at 3.51 (on a scale with a range from 17 to 113) (Summary of findings for the main comparison) and remission rates overall increased from 380 per 1000 (based on the median risk in the placebo group at post intervention) to 448 per 1000 (Summary of findings for the main comparison). Even for those drugs that had consistent evidence of efficacy across more than one outcome (fluoxetine and escitalopram), the reduction in average scores was 5.63 lower for those taking fluoxetine and 2.67 lower for those on escitalopram compared with those on placebo. Poznanski 1996 found a difference of 25 points on the CDRS-R scale between a clinically referred depressed group (n = 60) and a non clinical group (n = 223), and a difference of 19 points between clinically referred groups with (n = 60) and without depressive disorder (n = 18) (Poznanski 1996, pg 53). There was also a relatively small effect on functioning with those receiving fluoxetine and escitalopram having a score on average 3.08 higher and 2.28 points higher respectively than placebo on the CGAS (range 0 to 100). For fluoxetine, remission rates overall increased from 214 per 1000 (based on the median
risk in the placebo groups at post intervention) to 315 per 1000 (a difference of 101 with 95% confidence interval (CI) from 6 more to 231 more). While significantly more young people recover if on fluoxetine, the remission rates are relatively low overall indicating many young people do not experience a clinically meaningful reduction in symptoms. Methodological issues including large attrition rates and inappropriate outcome measurement, with the associated potential for selective reporting, make it difficult to draw conclusions about the clinical benefit.

In addition, the efficacy results need to be balanced with evidence about adverse outcomes. Over all drugs, the risk of a suicide-related outcome for those taking antidepressants was 58% (95% CI 2% to 245%) higher compared to those taking placebo. This equates to an increased risk in a group with a median baseline risk from 25 in 1000 to 40 in 1000 (Summary of findings for the main comparison). There was some variability in the risk of suicide-related outcomes across the drugs (I² = 22%; 95% CI 0% to 58%), but this was not statistically significantly different. Suicidal ideation was only measured in two trials with no effect of antidepressant treatment evident. Adverse events were greater for those taking an antidepressant, and there was no effect of antidepressant on the rate of trial completion.

There were few data available to investigate whether age modified the intervention effect. There was no evidence from the available data that age modified the effects of antidepressant medication. The evidence of the effectiveness of antidepressants for children was inconsistent, with a small overall reduction in depression symptoms (3.18) and remission rates in one study (Emslie 2002) of 44% for those receiving fluoxetine compared to 18% for those receiving placebo and in the other (Emslie 2006) 69% for those receiving escitalopram and 52% for those receiving placebo. For adolescents, there was consistent evidence across both these outcomes of antidepressants compared with placebo. However, the same cautions apply in terms of methodological considerations and the size of the effects.

**Overall completeness and applicability of evidence**

In this review, to our knowledge, we have presented data on efficacy and adverse outcomes, including suicide-related outcomes, from all published and unpublished trials examining the use of newer antidepressants for child and adolescent depressive disorder. Despite attempts to contact all trial authors, as well as pharmaceutical companies responsible for funding the included trials, there are many instances of missing data in terms of effect estimates. In two cases there is very limited reporting of trials by the Medicines and Healthcare Products Regulatory Agency (MHRA), with publication in peer-reviewed journals not yet available (Mirtazapine Trial 1 & 2). Likewise the trial by Simeon 1990, which was stopped early, has never been published. We were unable to obtain any further report of the trial Glod 2004, the preliminary findings of which were published in a conference abstract.

The comparator group has an impact on the size of the effect and, in this case, the size of the effect in the placebo groups in these trials has been commented on (e.g. Jureidini 2004) and authors of the included trial reports themselves have commented, suggesting, for example, that this may be to do with the large amount of contact trial participants receive. Trials consistently include regular (often weekly) assessments and in a significant number of trials some sort of supportive contact or therapy was allowed. The interaction between participants and trial investigators was seldom standardised, as shown in a trial specifically investigating this issue, and while this interaction is typical of what takes place in real world clinical encounters, it impacts in an unknown way on the detection of differences between the active drug and placebo (Dunlop 2010).

The characteristics of the participants also impact on the intervention effect. It is possible, for example, that the effect shown in the fluoxetine trials may be due to exclusion of placebo responders in the lead-in time to the start of the trial. The placebo remission rate was higher in trials of other compounds and has previously been cited as a cause for concern regarding the efficacy of selective serotonin reuptake inhibitors (SSRIs) (Newman 2004). Again, it is notable that in the trials of fluoxetine the attrition rate was consistently higher in the placebo group compared with the fluoxetine group. There were generally very high attrition rates in all of the trials and it is unclear what effect this has on treatment estimates. The young people in the trials are not likely to be representative of clinical populations typically seen in public child and adolescent mental health services as most trials included recruitment using advertisement, excluded many comorbid disorders, and in many trials excluded those who responded to placebo in the lead-in stage of the trial. Also excluded were those at risk of suicide despite suicide-related behaviours and comorbidity being significant features of clinically referred young people with depressive disorders (Birmaher 1996; Kovacs 1984; Marttunen 1998; Petersen 1993). The baseline severity of young people included was in the moderately severely ill range, with a large proportion of included participants experiencing their first episode of depression (although in many cases this first episode was of a long duration). The effectiveness of newer generation antidepressants in young people with more severe disorders and complex presentations, including comorbid conditions and suicide risk, is therefore unknown.

**Quality of the evidence**

There was limited information on the conduct of trials in relation to allocation concealment, blinding and compliance. Blinding is an issue when clinician-rated scales are the main outcome, particularly in the context of an inactive placebo where it may be possible to guess the assigned treatment group given side and other physiological effects likely in this group (Moncrieff 2004). In most cases the write-up simply indicated that the trial was dou-
ble-blind’, some stating that the placebo and medication capsules were identical and some stating that clinicians or trial personnel and participants were blinded. Only one trial specifically stated that outcome assessors were blinded.

The issue of reporting bias is important. Kirsch 2008 highlight in their meta-analysis of all trials of antidepressants submitted to the Food and Drug Administration (FDA) that effect sizes are smaller when unpublished studies are included and Turner 2008 showed that whether and how trials of antidepressants were published depended on the outcome of the trial. We located several trials that have not been fully reported or published at all. It is also worth noting that in many cases we were unable to obtain the required data from the published paper but had to contact authors or the pharmaceutical company. Reporting bias within the published reports of included trials was difficult to assess given the conduct of a trial can be obscured in the write-up for publication. Full and explicit reporting of changes in outcome definition was only undertaken by one investigator, however the primary outcome was reported and findings discussed (Emslie 1997; Jureidini 2004). The possibility of reporting bias was highlighted in a letter to the editor regarding post hoc alterations of response definitions in the trial by Keller 2001 (Jureidini 2003).

What level of improvement constitutes a meaningful clinical outcome is uncertain given response and remission were defined and reported variously both within and across trials, with the noted possibility of alteration of this definition, and the possibility of reporting bias as a result. There was evidence of inappropriate methods of imputation with trialists often using last observation carried forward data (Sterne 2009). It was often the case that some randomised patients were not included in the final analysis. The majority of trials were pharmaceutically funded. Two of the four fluoxetine trials were not pharmaceutically funded (Emslie 1997; TADS 2004) (the TADS trial had an unrestricted education grant from Eli Lily). Research has shown that across different health fields, pharmaceutically funded studies are more likely to have results favouring the pharmaceutical company’s product (Lexchin 2003; Sismondo 2008).

Measurement issues

A standard definition of remission or response would have been ideal; however, to calculate this individual patient data would have been necessary. Further, given a diagnosis of major depressive disorder on DSM criteria was an entry criterion for most of the trials, this may be considered the most desirable outcome measure. Additionally, given symptom improvement or resolution does not necessarily correlate with improvements in functioning (see Winters 2005 for a review), the latter would seem a more clinically important patient outcome to collect. However, this was inconsistently measured and reported on scales that often did not have established psychometric properties. In trials that used the Children’s Global Assessment Scale (CGAS) (an adaptation of the Global Assessment of Functioning (GAF) used in adults), there was some evidence that functioning was improved for those on an antidepressant compared with placebo. Self report data may also tap an outcome that is meaningful to the young person, however, few individual trials reported this.

The trials are designed only to examine the short-term effects of antidepressant medication, however, this does not preclude the possibility that the effectiveness of treatment is only apparent over a longer period of time. Long-term follow-up would be required to assess this.

Potential biases in the review process

It should be noted that the review process included collection of data from various sources. There were more complete data for the trials on paroxetine due to publication of trial reports by SmithKline Beecham on the internet. Details of aspects of trial methodology were relatively brief even in this case. Information and data from other trials were taken variously from scientific journal publications, from the MHRA data and, in some cases, obtained directly from trial authors and pharmaceutical companies. We were unable to obtain a large number of potentially relevant publications to screen for inclusion. The majority of these were conference proceedings and there is some evidence that such data are often not published and that publication is associated with positive results (Sherer 2007). However, funnel plots for the outcomes remission and suicide-related behaviour were not suggestive of small-study effects and, moreover, the contour-enhanced funnel plots did not indicate that statistically significant results were more likely to be reported.

Agreements and disagreements with other studies or reviews

The issue of the efficacy of antidepressants and the associated suicide risk has been the topic of much research, review and debate in the literature. Healy was one of the first to publish regarding the possibility of an increased risk of suicide associated with SSRIs (Healy 2003). Since then, observational studies have highlighted an association between antidepressant use and suicide risk in adolescents. For example, Olfson 2006 showed an association between use of antidepressants and suicide attempt in children and adolescents and Simon 2006b showed a greater risk of suicide attempt that resulted in hospitalisation for children and adolescents compared with adults.

Data on risk of suicide for children and adolescents have also come from meta-analyses based on trial data submitted to the FDA (Hammad 2006) and the Committee on Safety in Medicines in the UK (Dubicka 2006) that show similar results to our review.
These findings have more recently been extended to young adults (18 to 25-year olds) (Stone 2009). Additionally, Dubicka 2006 analysed these data by type of suicide-related outcome showing suicidal ideation in 1.2% of those on SSRIs compared with 0.8% on placebo (odds ratio (OR) 1.45; 95% CI 0.54 to 3.88), self harm in 3.3% of those on SSRIs versus 2.6% on placebo (OR 1.44; 95% CI 0.70 to 2.97) and attempts in 1.9% of those on an SSRI versus 1.2% on placebo (OR 1.70; 95% CI 0.76 to 3.81) (Dubicka 2006). Another review (Bridge 2007) calculated the risk difference for suicide-related behaviours for antidepressant versus placebo for major depressive disorder (MDD) (13 trials), obsessive-compulsive disorder (OCD) (six trials) and non OCD anxiety disorders (six trials). The risk difference for suicide-related behaviours was not statistically significant for MDD alone, although the risk ratio was 1.6; 95% CI 1.0 to 2.7 (Bridge 2007). The risk difference calculated by Bridge 2007 was 1% compared with a risk difference of 1.5% based on risk ratio (assuming a median baseline risk) calculated in this review.

Counter to this evidence showing an increase in suicide-related behaviours, several arguments have been mounted. Firstly, observational and ecological studies have shown no increased suicide risk related to antidepressant use. For example, observational studies by Valuck 2004 (a retrospective study) and Sondergard 2006 (a register-linkage study) showed no statistically significant increases in suicide attempt (hazard ratio (HR) 1.43; 95% CI 0.89 to 2.82) and completed suicide (RR 4.47; 95% CI 0.95 to 20.96) (respectively) for children and adolescents taking antidepressants. Two reviews of studies investigating this link highlighted that observational studies have not shown a strong association between antidepressants and suicide risk (Hall 2006; Isacsson 2010). Hall 2006 highlighted that observational studies have tended to show that those at increased risk of suicide were more likely to be prescribed an antidepressant (Hall 2006) and therefore the association between antidepressant use and adolescent suicide-related behaviours may be more likely to be explained by severity of depression, and not caused by the antidepressant (Friedman 2007; Simon 2006). However, issues of potential confounding bias arising in observational studies are minimised in trials where, on average, those in the intervention and control groups are comparable in both measured and unmeasured confounders.

Hall 2006 and Isacsson 2010 have highlighted that the majority of ecological studies have shown that suicide mortality has decreased when SSRI use has increased in various countries or regions (Hall 2006). However, these studies either have not included children and adolescents or analysed this age group separately, with the exception of Olsson 2003 in the US. Olsson 2003 showed that increasing use of antidepressants was associated with a decreased suicide rate. A subsequent study using US and Dutch data showed a decrease in SSRI prescriptions associated with an increased suicide rate in both countries (Gibbons 2007).

There are shortcomings to these types of ecological studies, which have been discussed in the debate in this area. It is commonly acknowledged that ecological studies are not able to establish a causal link. For example, it could be that there are lower suicide rates in countries with less stigma associated with seeking intervention for mental health disorders, where antidepressant prescriptions rates are therefore higher (Gunnell 2004; Simon 2006). Ecological studies have focused on short time periods, for example, Healy 2009 and Reseland 2008 contend that ecological studies have omitted data from the 1960s and 1970s when suicide rates climbed despite the largest increase in antidepressant use seen in the last few decades; Safer 2007 similarly argues that time periods prior to the introduction of SSRIs have not been included when drops in suicide rates were observed. Another issue of ecological studies is that the relationships observed between variables at the aggregated level may not be the same as those observed at the individual level. An example of this is the possibility that increased use of antidepressants may be due to chronic users not new users, whose risk of treatment-induced suicide is less (Reseland 2008). There are issues of confounding, for example fluctuations in suicide rates may be due to cultural and religious factors (De Leo 2002). Further, there is the issue of redefinition of the outcome over time. For example, reanalysis of data on suicide rates, antidepressant sales and autopsy in Nordic countries highlighted the possibility that observed decreases in suicide rates may be due to falling autopsy rates, and an associated increase in the rate of deaths from unspecified causes (Reseland 2008).

Finally, the observation of increased suicide rates associated with a decrease in the rate of SSRI prescriptions may be because the recent censure of SSRIs has resulted in pessimism about being able to provide effective treatment. This may have caused both a decrease in help seeking and a disinclination to diagnose depressive disorders, supported by data showing decreased rates of diagnosis for child and adolescent depression in the USA (Libby 2007).

The fact that there were no reports of completed suicide in a total sample of 2240 young people has been highlighted. However, suicide is a rare event and much larger sample sizes with longer follow-up would be needed to assess the risk fully. Healy 2009 cautions that it is more accurate to state that no suicides were recorded and notes that large loss to follow-up makes it possible that suicides did occur. Research suggests that the best predictor of eventual suicide completion is previous suicidal ideation and suicidal behaviour so that an increase in rates of these outcomes may increase the risk of future suicide completion (Andrews 1992; Brent 1986; Brent 1993; Lewinsohn 1996). The trials included in our review and others do not provide long enough follow-up to determine whether short-term increased risk of suicide-related outcomes is subsequently followed by a longer-term risk reduction.

An increase in risk followed by a steadily decreasing risk has been shown within one month of starting antidepressant use in one trial of adults (Jick 2004). Data on timing of suicidal risk has been analysed from the TADS 2004 trial and showed that there was no decrease in risk after one month as seen in adult data, again meaning it is unclear if there is a longer-term risk reduction.
In all reviews the rates of suicide-related behaviour are much lower than reports of suicidal ideation and behaviour in adolescents from the community. In some population-based studies suicidal ideation is reported by as many as 12% to 23% of young people and suicide attempts by 4% to 8% of adolescents aged 13 to 18 years (AHRG 2003; Grunbaum 2002; Lewinsohn 1996; Sawyer 2001). This could be explained by exclusion of those at risk of suicide from all but two trials (Emslie 2002; Von Knorring 2006). Most trials also excluded those with many co-morbid conditions. Co-morbidity is related to an increased risk of suicidal ideation and suicidal behaviours (Andrews 1992; Asarnow 1992; Brent 1986; Esposito 2002; Kovacs 1993; Shaffer 1996; Wetzel 1996).

The findings regarding an increased risk of suicide-related behaviours need to be balanced with concerns regarding the risk of untreated depression and the need to balance benefits and harms (AACAP 2004; Ebmeier 2006; Simon 2006). Several reviews of the efficacy of SSRIs in children and adolescents with depression have been published. Earlier reviews based conclusions on narrative summaries of individual trial results (Brent 2004; Cheung 2005; Wagner 2005) not meta-analyses. Of these, the conclusions of Cheung 2005 are the most conservative, stating data are limited, commenting specifically on the inappropriateness of the outcomes used and cautioning clinicians to consider the use of SSRIs carefully.

A number of meta-analyses have also been published. In earlier meta-analyses Jureidini 2004 highlighted methodological problems, particularly regarding reporting, and concluded cautiously that there is only a small benefit of SSRIs that should be balanced with the risks. In contrast Cohen 2004 concluded SSRIs are an effective treatment for adolescent depression based on data published up to that point. In the same year, a review by Whittington 2004 highlighted the change in risk-benefit profile when unpublished data were included; their inclusion resulted in a favourable risk-benefit profile only for fluoxetine, with a number needed to treat to benefit (NNTB) of 6 (95% CI 4 to 15) for remission, and 5 (95% CI 4 to 13) for response. More recently, Taspakis 2008 has published a systematic review including meta-analyses of any antidepressant (including tricyclic antidepressants (TCAs), SSRIs, monoamine oxidase inhibitors (MAOIs) and new antidepressants) for children and adolescents up to the age of 20 with a depressive disorder. The authors’ conclusions were cautious, highlighting limited efficacy, particularly for children and in studies that combine adolescents and children. They found little appreciable difference between different types of antidepressants, however, suggesting that fluoxetine may be more effective, especially for adolescents. Similar to our findings, they questioned the appropriateness of outcome measures and noted that the young people included in trials may not be representative of more classic ‘adult major depression’ and may be less severe that young people typically seen in clinical practice.

In a meta-analysis of antidepressants for all age groups, Ioannidis 2008 questioned the appropriateness of outcome measures used and highlighted issues related to selective and distorted reporting and interpretation, calling into the question the effectiveness of antidepressants even in adult populations.

The results of our review present a dilemma for those treating young people with depressive disorders. While overall the reduction in depression symptoms is statistically significant, there are questions about the clinical effectiveness. The trials are of young people not representative of those typically presenting for treatment in clinics and furthermore they had some significant methodological shortcomings, making it difficult to draw firm conclusions. Potential benefit must be balanced with the finding that SSRIs are associated with a statistically significant increased risk of suicide-related behaviour (a combination of suicidal ideation and definitive suicidal behaviour). Much debate on this matter has taken place, with variable views.

While there is a lack of power to adequately examine rare events such as suicide-related outcomes in trials, meta-analysis offers a method for obtaining reliable evidence for these rare outcomes across trials. Given a lack of consistent measurement of various aspects of suicide risk, the clinical implications of the findings are still somewhat unclear.

It is unknown how children and adolescents with a depressive disorder and co-morbid conditions, who are at risk of suicide (i.e. those more typical of the young people who present at health services), would respond to SSRIs. Overall, the data regarding the benefits of SSRIs for child and adolescent depression are far from compelling while the information on the risks is limited.

Clinically, it must be kept in mind that there are significant risks in not treating depressive disorder, which has an increased risk of suicide completion, as well as impacts on academic and social functioning (Brent 2002; Ebmeier 2006; Fleming 1993; Lewinsohn 1998; NHMRC 1997; Rao 1995).

AUTHORS’ CONCLUSIONS

Implications for practice

The evidence for the effectiveness of newer generation antidepressants compared with placebo in the treatment of depressive disorder in children and adolescents is not compelling; the overall effects of antidepressants compared with placebo were not modified by drug. The methodological shortcomings of the trials make it difficult to interpret outcome data on the efficacy of newer generation antidepressant medications. This is a particularly unsatisfactory since large numbers of children and adolescents have participated in trials, and we are still unable to answer the important clinical question of whether antidepressant medications are effective in treating depressive disorders. The search for treatments that reliably lead to good clinical outcomes must continue.

Even when there is evidence that newer generation antidepressants reduce depression symptom severity, it is unclear whether the dif-
ference in effect between antidepressants and placebo reflects a difference that is of clinical importance to patients. As trials have largely been done in children and adolescents with no co-morbid conditions and with no significant suicidal ideation, it is unclear how children and adolescents with more serious difficulties and those at risk of suicide would respond. There is evidence to suggest an increased risk of suicide-related behaviours (combined suicidal ideation and definitive suicidal behaviour) in those treated with antidepressant medication, but the importance of this is unclear as is the association between antidepressant medication and suicide completion. Untreated depressive disorder is associated with the risk of completed suicide and impacts on academic and social functioning.

For clinicians, the results of the review may mean that the threshold of severity for treatment of a depressive disorder with antidepressant medication is raised. Clinicians should make every effort to present the information on the potential benefits and risks of SSRIs, including the risks of untreated depression, and together with the child or adolescent and their family, consider the various options for treatment. This should include consideration of psychological treatments such as cognitive behavioural therapy and other non medication options. The risk of suicide should be assessed and, if medication is used, this should be monitored particularly closely. If a decision to use medication is agreed, then fluoxetine might be considered given it is recommended as first-line medication in guidelines (McDermott 2011; NICE 2005), although based on this review no definitive recommendations can potentially be made until the comparative effectiveness of individual drugs is examined in a multiple-treatment meta-analysis.

Given the evidence does not clearly answer questions about the effectiveness and harms of newer generation antidepressants, there is a need for further research.

Implications for research

It is clear from the results that we need more effective treatments for depressive disorders in young people. The debate about efficacy and risk of suicide illustrates that there is no one clearly effective treatment. Young people with a depressive disorder who present for treatment are likely to be different to those in the included trials in this review; moreover those presenting for treatment in clinical services are heterogenous. Trials should include young people more typical of those presenting to clinical services and allow analysis of different subgroups of these young people. This may be an important avenue of new research, for example, there may be a genetic underpinning to medication responsiveness.

Trials that are undertaken should address the methodological shortcomings identified in this review, including adequate blinding, particularly of outcome assessors, consistent definition and use of clinically important outcomes and longer-term follow-up.

Within the context of the currently available trial data, individual patient data meta-analyses may be useful in examining whether the effect of treatment differs in particular subgroups.

In the meantime, given clinicians require guidance in terms of which individual antidepressant medication to use, in order to more robustly examine the comparative efficacy of these compounds, a multiple-treatment meta-analysis should be undertaken.

Acknowledgements

Alison Ward for her contribution to the protocol, data extraction and some input on the write-up of the review.

Steve McDonald, Australasian Cochrane Centre assisted with the development of the search strategy for the original review.

The CCDAN editorial base team assisted at all stages with helpful comments and guidance, including double data checking for the earlier version of the review; in this version of the review they have provided support in contacting pharmaceutical companies for additional data.

The editors and peer reviewers assisted with editorial comments at all stages of the review.

Trialists who provided data including Dr Graham Emslie, Dr Robert Milin, Professor Martin Keller and Professor John March.

Pharmaceutical companies who provided data on the web (SmithKline Beecham) and provided data as requested (Dr Jennie Jacobson from Eli Lilly).

MHRA for providing reports of trial data.

| Methods | Trial design: randomised controlled trial; single site  
|         | Power calculation: 0.90 power to detect a large effect size (0.80)  
|         | Use of diagnostic criteria (or clear specification of inclusion criteria): DSM-IV-TR criteria for depressive disorder plus a score of 13 in the DSDR  
|         | Intervention integrity: not described  
|         | Outcome measures described or validated measures used: yes  
|         | Follow-up assessment points: weekly for 7 weeks  
|         | No. crossed: none  
|         | Funded by: Eli Lilly provided fluoxetine and placebo  

| Participants | Setting of care: outpatient  
|             | Recruitment: no statement  
|             | Mean age (SD): intervention = 13.3 (3.16); control = 11.5 (1.58)  
|             | Age range: 8 to 14  
|             | Gender (F:M): intervention = not stated; control = not stated  
|             | Methods used to diagnose: DSM-IV using semi-structured interview; The Mini International Neuropsychiatric Interview for children and adolescents (MINI-KID)  
|             | Diagnosis: MDD  
|             | Baseline severity of depression: not reported  
|             | Length of current episode: not reported  
|             | % first episode: not reported  
|             | Co-morbidity (intervention): not reported  
|             | Co-morbidity (control): not reported  
|             | Location: Mexico  
|             | Inclusion criteria: major depressive disorder (DSM-IV-TR) plus a score of 13 in the DSDR  
|             | Exclusion criteria:  
|             | History of chronic physical illness, intellectual disability, bipolar disorder, substance use or dependence, Attention Deficit Hyperactivity Disorder, severe anxiety, behavioural disorder, hospital admission or increased treatment intensity due to a depressive episode in the preceding 4 weeks, antidepressive treatment in the preceding 4 weeks, any lab test which was considered to be abnormal by the clinician, oppositional defiant disorder  
|             | Exclusion of suicidality: suicide attempt in the preceding 4 weeks  

| Interventions | Intervention group  
|              | Drug: fluoxetine  
|              | Dosage: 20 mg  
|              | Regimen: daily  
|              | Length of treatment: 6 weeks  
|              | Control group: placebo  

| Outcomes | Definition and assessment of response: we used OC response data defined as 50% reduction in HDRS scores (they stated they used CGI-I score of 1 or 2; 50% reduction in DSRS and HAM-D scores

Location: Argentina, Belgium, Canada, Holla, Italy, Mexico, South Africa, Spain, United Arab Emirates, United Kingdom

Inclusion criteria: unipolar MDD for at least 8 weeks’ duration; negative pregnancy test

Exclusion criteria: prepubertal; diagnosis of Conduct Disorder, autism, Pervasive Developmental Disorder, organic psychiatric disorder including schizophrenia and epilepsy; Obsessive Compulsive Disorder, panic disorder, social phobia, PTSD that preceded MDD; medical illness that contraindicated use of paroxetine; previous response to psychotherapy; planned long-term psychotherapy; Electroconvulsive Therapy (ECT) in previous 3 months or planned for trial period; drug or alcohol dependency; concomitant psychotropic medication or other drugs interfering with Central Nervous System (CNS) activity; use of sumatriptan, oral anticoagulants or type 1C antiarrhythmics, i.e. encainide, flecaainide, lorcainide and propafenone; previous use of paroxetine or other SSRIs; sensitivity to SSRIs; sexually active and not using contraceptive or pregnant or lactating; use of other investigational drug

Exclusion of suicidality: although a history of suicide attempt(s) was not exclusionary, patients with current serious suicidal ideation were excluded

### Interventions

**Intervention group**
- Drug: paroxetine
- Dosage: 20 to 40 mg
- Regimen: daily
- Length of treatment: 12 weeks

**Control group:** placebo pill

### Outcomes

Definition and assessment of response: we used OC response defined as ≥ 50% MADRS (they used responders defined as at least a 50% reduction on MADRS. Post hoc analysis on responder rate based on a CGI-I score of 1 or 2 was also conducted).

Depressive symptoms: change from baseline in the K-SADS-L depression sub-scale score

Functioning: Children's Global Assessment Scale (C-GAS)

Suicidal behaviour: FDA data; no report of continuous measure

Other measures: Montgomery-Asberg Depression Rating Scale (MADRS); K-SADS-L; Clinical Global Impressions Scale Improvement (CGI - Improvement); Mood and Feeling Questionnaire; adverse events

### Notes

Additional data were sought and received from the authors

MHRA # 377

MHRA contacted for additional data some of which were provided

Data in MA taken from GlaxoKline Beecham web-based report

Type of data used for remission/response: last observation carried forward

Co-morbidity (control): none 11; dysthymia 14; anxiety disorders 22; ADHD 13; ODD/CD 16  
Location: USA  
Inclusion criteria: non psychotic MDD, single or recurrent; good general medical health; normal intelligence  
Exclusion criteria: bipolar I and II; psychotic depression; independent sleep-wake disorder; alcohol and other substance abuse; anorexia nervosa; bulimia nervosa; previous adequate treatment with fluoxetine; at least 1 first-degree relative with bipolar I disorder  
Exclusion of suicidality: not specifically stated

### Interventions

**Intervention group**  
Drug: fluoxetine  
Dosage: 20 mg  
Regimen: taken daily  
Length of treatment: 8 weeks (following acute treatment, participants were given the option to continue treatment blindly or be treated openly)  
Control group: placebo pill

### Outcomes

Definition and assessment of response: we used remission CDRS-R ≤ 28 (they used responders defined as CGI improvement rating of 1 or 2)  
Depressive symptoms: Children’s Depression Rating Scale - Revised (CDRS-R)  
Functioning: Children’s Global Assessment Scale (CGAS)  
Suicidal behaviour: FDA report; no report of continuous measure  
Other outcomes: Clinical Global Impressions Scale Improvement (CGI); Children’s Depression Inventory (CDI); Beck Depression Inventory (BDI); Weinberg Screening Affective Scale (WSAS); Brief Psychiatry Rating Scale - Children’s (BPRS-C)

### Notes

Additional data were sought and supplied by the authors. Data in the MA for child, adolescent and total populations taken from paper publication and these additional data.  
Child and adolescent data from author. MHRA # X065  
MHRA contacted for additional data some of which was provided  
Type of data used for remission/response: last observation carried forward

</tr>
</tbody>
</table>
### Emslie 1997

**Other bias**

Unclear risk

Contact: participants were seen weekly for 8 weeks and outcomes were measured at each visit (pg 1033). No other details given.

Screening: phone screening followed by 3 independent full evaluations over 3 weeks.

Placebo lead-in: 1 week single-blind.

Baseline imbalance: pg1033 states there were not differences on any clinical or demographic features except the fluoxetine group had a greater incidence of life time anxiety disorders.

Other: small trial; Beck Depression Inventory and Childrens Depression Inventory scores combined to give a total score; while stratified for age, no outcome reporting by age was given.

### Emslie 2002

**Methods**

- Trial design: randomised controlled trial; multicentre
- Power calculation: yes
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes
- Intervention integrity: not described
- Outcome measures described or validated measures used: yes
- Follow-up assessment points: post assessment
- No. crossed over: none
- Funded by: Eli Lily

**Participants**

- Setting of care: outpatients
- Recruitment: academic hospitals and private research psychiatric clinics as well as newspaper and radio recruitment
- Mean age (SD): intervention = 12.70 (2.46); control = 12.69 (2.67)
- Age range: 8 to < 18 years
- Gender (F:M): intervention = 54:55; control = 54:56
- Methods used to diagnose: DSM-IV Diagnostic Interview for Children and Adolescents (DICA) interview, CDRS-R ≥40 and CGI = 4, 3 independent diagnostic interviews and a 1-week placebo lead in
- Diagnosis: MDD
- Baseline severity of depression: CDRS-R mean (SD) score: intervention = 57.1 (9.9); control = 55.1 (11.8); CGI intervention 4.5 (0.6); placebo 4.4 (0.6)
- Length of current episode: (mean weeks) intervention: 60.44; placebo: 61.29
- % first episode: intervention 79.8%; placebo 78.2%
- Co-morbidity (intervention): ADHD 16; ODD 17; CD 3
- Co-morbidity (control): ADHD 15; ODD 17; CD 1
- Location: USA
- Inclusion criteria: outpatients; aged 8 to < 18; primary diagnosis of non psychotic major depressive disorder, single or recurrent; depressive symptoms of at least moderate severity; no clinically significant ECG abnormalities; able to keep appointments; normal
intelligence as judged by investigator
Exclusion criteria: serious illness that was not stabilised; abnormal thyroid function; seizure disorder; bipolar I or II; sleep-wake disorder; psychotic depression; anorexia nervosa; bulimia nervosa; borderline personality disorder; substance abuse disorder; 1 or more first degree relatives with bipolar I disorder; organic brain diseases; previous failed response to antidepressant medication; prior adequate treatment with fluoxetine; receipt of fluoxetine within 3 months prior to trial entry; regular use of other psychotropic drugs
Exclusion of suicidality: serious suicide risk (no further definition)

### Interventions

**Intervention group**
- **Drug:** fluoxetine
- **Dosage:** 20 mg
- **Regimen:** 1 week 10 mg daily, then 20 mg daily for 8 weeks
- **Length of treatment:** 9 weeks
- **Control group:** placebo pill

### Outcomes

**Definition and assessment of response:** we used remission CDRS-R \( \leq 28 \) (they used responders defined as CGI improvement rating of 1 or 2 or at least a 30% reduction on CDRS-R. Remission was defined as a score of \( \leq 28 \) on the CDRS-R.
- **Depressive symptoms:** Children's Depression Rating Scale - Revised (CDRS-R)
- **Functioning:** Global Assessment of Functioning Scale (GAF)
- **Suicidal behaviour:** FDA report; no report of continuous measure

**Adverse events**
- **Other outcomes:** Clinical Global Impressions Scale Severity (CGI-Severity), Clinical Global Impressions Scale Improvement (CGI - Improvement), Hamilton Anxiety Rating Scale (HAMA), Beck Depression Inventory (BDI)
- **Children's Depression Inventory (CDI), Montgomery-Asberg Depression Rating Scale (MADRS)**

### Notes

Additional data were sought from authors. They did not have the additional data but gave a contact in Eli Lily. Eli Lily provided additional data. Data in the MA from the paper and from additional data supplied by Eli Lily.
- **MHRA # HCJE**
- **MHRA contacted for additional data some of which were provided**
- **All data from paper (Table 3)**

Assume the P value (that goes with the adjusted treatment effect of 7.1; effect size 0.51; CI 3.3, 10.9) is adjusted but the means presented in table 3 and provided by the author are probably not. JM calculated SE from SDs (in STATA file) for depression symptom outcome

Type of data used for remission/response: last observation carried forward

### Methods

- **Trial design:** randomised controlled trial; multicentre
- **Power calculation:** yes
- **Use of diagnostic criteria (or clear specification of inclusion criteria):** yes
- **Intervention integrity:** yes - "Every effort was made to encourage patient compliance with the dosing regimen as per protocol. All patients were instructed to return their medication bottles with any unused drug to the investigator when they returned for each visit". Section 3.6 compliance with trial medication, Final Report
- **Outcome measures described or validated measures used:** yes
- **Follow-up assessment points:** post intervention
- **No. crossed over:** none
- **Funded by:** GlaxoSmithKline

### Participants

- **Setting of care:** outpatient
- **Recruitment:** no information
- **Mean age (SD):** intervention = 11.9 (3.00); control = 12.1 (2.95)
- **Age range:** 7 to 17 years
- **Gender (F:M):** intervention = 48:53; control = 47:55
- **Methods used to diagnose:** DSM-IV, K-SADS-PL using 1-week screening phase
- **Diagnosis:** MDD
- **Baseline severity of depression:** CDRS-R mean (SD) score: intervention = 60.7 (9.37); control = 62.6 (8.96); CGI intervention 4; CGI placebo 4
- **Length of current episode:** (mean months) intervention: 26.9 (28.62); placebo: 24.9 (27.08)
- **% first episode:** intervention 53.5%; placebo 52.9%
- **Co-morbidity (intervention):** ODD 5; GAD 4; overanxious disorder 3; attention deficit disorder 3; separation anxiety disorder 2; simple phobia 1; PTSD 1; enuresis 1; adjustment disorder with depressed mood 0
- **Co-morbidity (control):** ODD 4; GAD 1; overanxious disorder 1; attention deficit disorder 1; separation anxiety disorder 0; simple phobia 0; PTSD 0; enuresis 0; adjustment disorder with depressed mood 1
- **Location:** USA and Canada
- **Inclusion criteria:** 7 to 17 years; MDD
- **Exclusion criteria:** clinically predominant Axis I disorder other than MDD; history of psychotic episode or disorder; bipolar disorder; mental retardation or Pervasive Developmental Disorder; substance abuse or dependence within 3 months of screening or current positive test on drug screen; epilepsy; ECT within 3 months of screening; lactating or pregnant; sexually active female and not using contraception; requirement of concurrent psychotherapy; clear history of non response to SSRIs
- **Exclusion of suicidality:** suicidal or homicidal risk (no further definition)

### Interventions

- **Intervention group**
  - **Drug:** paroxetine
  - **Dosage:** 10 to 50 mg
  - **Regimen:** week one 10 mg daily with option to increase up to 10 mg weekly to a maximum of 50 mg; reduction/tapering over 4 weeks post 8-week treatment
  - **Length of treatment:** 8 weeks
- **Control group:** placebo pill
### Outcomes

- **Definition and assessment of response:** We used OC remission CDRS-R ≤ 28 for total; OC response for child and adolescent data CGI ≤ 2 (they used response defined as CGI Improvement of 1 or 2).
- **Depressive symptoms:** Children's Depression Rating Scale - Revised (CDRS-R)
- **Functioning:** Global Assessment of Functioning (GAF)
- **Suicidal behaviour:** Report of events based on Columbia classification; no report of continuous measure
- **Adverse events:** Gathered by spontaneous report from patient and family
- **Other outcomes:** Clinical Global Impressions Scale Severity (CGI-Severity); Clinical Global Impressions Scale Improvement (CGI-Improvement); Kutchers Adolescent Depression Rating Scale (KADS)

### Notes

- MHRA #701
- MHRA contacted for additional data some of which were provided
- Data in MA taken from GlaxoKline Beecham web-based report

### Emslie 2009

**Methods**
- Trial design: randomised controlled trial; multicentre  
- Power calculation: yes  
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes  
- Intervention integrity: not described  
- Outcome measures described or validated measures used: yes  
- Follow-up assessment points: post-intervention  
- No. crossed over: none  
- Funded by: Forest laboratories

**Participants**
- Setting of care: outpatient  
- Recruitment: no information  
- Mean age (SD): intervention = 14.7 (1.6); control = 14.5 (1.5)  
- Age range: 12 to 17 years  
- Gender (F:M): intervention = 92:63; control = 92:65  
- Methods used to diagnose: DSM-IV with duration of current episode at least 12 weeks at screening confirmed by K-SADS. At screening and baseline a CDRS-R score of ≥ 45 and a CGI-S score of ≥ 4. Screening period of 2 weeks, and a single-blind placebo run-in of 1 week during 2nd week of screening.  
- Diagnosis: MDD  
- Baseline severity of depression: CDRS-R mean (SD) score: intervention = 56.0 (0.66); control = 57.6 (0.66); CGI intervention 4.6 (0.05); CGI placebo 4.4 (0.04)  
- Length of current episode: (mean months) intervention 15.7 (17.4); placebo 16.5 (15.4)  
- % first episode: intervention 70.3%; placebo 72%  
- Co-morbidity (intervention): previous and/or ongoing secondary psychiatric disorder 16.6%  
- Co-morbidity (control): previous and/or ongoing secondary psychiatric disorder 12.9%  
- Location: USA
Emslie 2009  *(Continued)*

| Inclusion criteria: current DSM-IV defined MDD episode of at least 12 weeks, CDRS-R score $\geq 45$ at screening and baseline visits, CGI-S score of $\geq 4$ and a score of $\geq 80$ on the Kaufman Brief Intelligence Test
| Exclusion criteria: a principal diagnosis meeting DSM-IV criteria for an Axis 1 disorder other than MDD or who currently met DSM-IV criteria at screening for attention-deficit/hyperactivity disorder, obsessive-compulsive disorder, post-traumatic stress disorder, bipolar disorder, pervasive developmental disorder, mental retardation, conduct disorder, or oppositional defiant disorder; or who had any psychotic features or a history of any psychotic disorder; or any personality disorder that as judged by the investigator, would interfere with participation in the trial; a history of manic, or hypomanic episodes, a history of bulimia anorexia nervosa or substance abuse or dependence within the last year
| Exclusion of suicidality: patients considered a suicide risk by the investigator, including those who had active suicidal ideation, had made a suicide attempt, or had ever been hospitalised because of a suicide attempt

**Interventions**

| Intervention group
| Drug: escitalopram
| Dosage: 10 to 20 mg/day
| Regimen: daily
| Length of treatment: 8 weeks
| Control group: placebo pill

**Outcomes**

| Definition and assessment of response: we used remission CDRS-R $\leq 28$ (they used the Clinical Global Impressions-Improvement Scale (CGI-I). A score of 1 (very much improved) or 2 (much improved) or CDRS-R reduction of $\geq 40\%$ defined response (remission CDRS-R $\leq 28$))
| Depressive symptoms: the Childrens Depression Rating Scale (CDRS-R; Poznanski 1996)
| Functioning: Children’s Global Assessment Scale (C-GAS; Shaffer 1985)
| Suicidal behaviours: Modified Columbia Suicide Severity Rating Scale (MC-SSRS) report of suicidal ideation, presence and type of suicidal behaviour since last visit; continuous measure using the Suicidal Ideation Questionnaire-Junior High School Version (SIQ-JR; Reynolds 1987)
| Adverse events: either spontaneously reported by patient or parent, or noted by investigator

**Notes**

| Type of data used for remission/response: last observation carried forward

**Risk of bias**

### Keller 2001

#### Methods
- Trial design: randomised controlled trial; multicentre
- Power calculation: yes
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes
- Intervention integrity: yes - “Compliance with taking trial medication was assessed by recording the amount of drug dispensed, taken, and returned in the CRF for each patient”. Section 3.6 Final report.
- Outcome measures described or validated measures used: yes
- Follow-up assessment points: post intervention
- No. crossed over: none
- Funded by: GlaxoSmithKline

#### Participants
- Setting of care: outpatient
- Recruitment: no information
- Mean age (SD): intervention = 14.8 (1.6); control = 15.1 (1.6)
- Age range: 12 to 18 years
- Gender (F:M): intervention = 58:35; control: 57:30
- Methods used to diagnose: DSM-IV diagnosis confirmed by K-SADS-L and current duration of episode at least 8 weeks, a score of ≥ 12 on the HAM-D, a CGAS score of ≥ 60; screening period of 7 to 14 days, no placebo run-in phase
- Diagnosis: MDD
- Baseline severity of depression: K-SADS 9-item depression score; intervention = 28.25; control = 28.84. C-GAS mean (SD) score: intervention = 42.7; control = 42.8; CGI not reported
- Length of current episode: (mean months) intervention: 14 (18); placebo: 13 (17)
- % first episode: intervention 81%; placebo 77%
- Co-morbidity (intervention): any diagnosis 41; anxiety disorder 19; externalising disorder 25
- Co-morbidity (control): any diagnosis 50; anxiety disorder 26; externalising disorder 26
- Location: USA and Canada
- Inclusion criteria: MDD of at least 8 weeks duration; at least 80 on the Peabody Picture Completion Task; Medically Healthy
- Exclusion criteria: bipolar disorder; schizoaffective disorder; eating disorder; alcohol or substance abuse disorder; Obsessive Compulsive Disorder; autism/pervasive developmental disorder; organic brain disorder; PTSD within 12 months of trial entry; current psychotropic drug use; trial of antidepressant medication within 6 months of trial entry
**Keller 2001** *(Continued)*

<table>

**Outcomes**

| Definition and assessment of response: we used OC response HAM-D \( \leq 8 \) or \( \geq 50\% \) reduction in baseline HAM-D (they used responders defined as \( = 8 \) or less on HAM-D or at least 50% decrease from baseline) |
| Depressive symptoms: depression items from K-SADS-L |
| Functioning: Autonomous Function Checklist |
| Suicidal behaviours: FDA data; no report of continuous measure |

**Adverse events**

| Other measures: HAM-D; Clinical Global Impressions Scale Improvement (CGI - Improvement); Self Perception Profile; Sickness Impact Scale |

**Notes**

| Additional data were sought from the authors. They did not have the data required but provided a contact from GlaxoSmithKline who responded to inform us of the trial information now published on the web. |
| MHRA # 329 |
| MHRA contacted for additional data some of which were provided |
| Data in MA taken from GlaxoSmithKline Beecham web-based report |
| GlaxoSmithKline web publication |
| Type of data used for remission/response: last observation carried forward |

</table>

| Selective reporting (reporting bias)          | High risk     | Multiple measurement of depression outcome (HAM-D, HAM-D depressed mood item, depression item of K-SADS-L and 9-item depression sub-scale of the K-SADS). Response data given as percentages. In a letter to the editor Jureidini 2003 states that the definition of response is changed so that a significant result can be reported. Overall adverse event rate not described. Kennard 2006 (TADS) states that Keller had remission definition of HAM-D < 8, although Keller describes this in the methods section |
Other bias | High risk |
---|---|
Contact: participants were seen weekly and undertook assessments at each visit. Supportive case management was provided to all subjects at each visit (interpersonal or cognitive behavioural psychotherapeutic interventions were strictly prohibited) (pg 764)
Screening: 7 to 14-day screening period with no detail about number of assessments during this screening phase
Placebo lead-in: no
Baseline imbalance: treatment groups stated to be similar at baseline for demographic and psychiatric profile (pg 765). These features are described in Table 1.

### Mirtazapine Trial 1

#### Methods
- Trial design: randomised controlled trial; multicentre
- Power calculation: not stated
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes
- Intervention integrity: yes - “Plasma samples, for the purpose of measuring mirtazapine, (Org 3770) concentrations, were to be collected on trial Days 28 and 56 (or the subject’s final day of treatment)” pg 4. Company trial report
- Outcome measures described or validated measures used: yes
- Follow-up assessment points: post intervention
- No. crossed over: none
- Funded by: Organon International

#### Participants
- Setting of care: outpatients
- Recruitment: through clinical practice of investigators, referrals and/or advertisements for volunteers
- Mean age (SD): intervention = 12.3; control = 12.4
- Age range: 8 to 18 years
- Gender (F:M): intervention = 39:43; control: 25:19
- Methods used to diagnose: DSM-IV diagnosis confirmed by K-SADS-L and baseline score of $\geq 15$ on 1st 17 items of HAM-D (21-item), a CGAS score of $< 70$; CDRS-R $\geq 40$; screening period not stated
- Diagnosis: MDD
- Baseline severity of depression: CDRS-R mean (SD) score: intervention = 50.93; control = 51.93
- Length of current episode: not stated
- % first episode: not stated
- Co-morbidity (intervention): not stated
- Co-morbidity (control): not stated
- Location: USA
Mirtazapine Trial 1  *(Continued)*

| Inclusion criteria: current episode of MDD (as defined by DSM-IV criteria, with a primary diagnosis of major depressive disorder on the Kiddie-SADS P-L (Kiddie schedule for affective disorders and schizophrenia - present and lifetime). Baseline score of >15 on the 1st 17 items of the Hamilton Scale for Depression, 21 items (HAM-D 21), <70 on the Children's Global Assessment Scale (C-GAS), and a Children's Depression Rating Scale-Revised (CDRS-R) score of ≥40
Exclusion criteria: concurrent psychiatric diagnosis of anorexia or bulimia, past history of eating disorder, concurrent diagnosis of obsessive compulsive disorder or schizophrenia, bipolar disorder (I or II) or parental history of bipolar I disorder, drug/and or alcohol abuse
Exclusion of suicidality: serious suicide attempt during the current major depressive episode, or any previous suicide attempt resulting in hospitalisation |
|---|
| Interventions | Intervention group
Drug: mirtazapine
Dosage: 15 to 45 mg
Regimen: starting dose 15 mg with increase to 30 to 45 mg in 15 mg increments during subsequent weeks (to 28 days)
Length of treatment: 8 weeks
Control group: placebo pill |
| Outcomes | Definition and assessment of response: not stated
Depressive symptoms: CDRS-R clinician rating; HAM-D 21 self rating
Functioning: C-GAS used but no report of data
Suicidal behaviours: events reported as adverse events; no report of continuous measure
Other measures: Clinical Global Impressions (CGI), Self Report Childhood Anxiety Related Disorder (SCARED), Connors’ Global Index (Parent and Teacher Versions) |
| Notes | **Risk of bias** |

| Incomplete outcome data (attrition bias)      | Unclear risk | Number eligible: not stated  
Number randomised: mirtazapine: 82; placebo: 44; total: 126  
Number started trial: mirtazapine: 82; placebo: 44; total: 126  
Number of withdrawals: mirtazapine: 13; placebo: 9; total 22  
Number analysed post intervention: mirtazapine: 82; placebo: 44; total: 126  
Reasons for drop out: MHRA reports drops across the 2 mirtazapine trials: 9 (5.3%) patients discontinued due to an adverse event in the mirtazapine group compared with 3 (3.4%) in the placebo-treated group. The most common adverse treated event leading to discontinuation in the acute phase in the mirtazapine treated group was weight gain. Weight gain (31.8% versus 3.4%), somnolence (38.8% versus 6.8%), headache (35% versus 23%), fatigue (19.4% versus 11.4%) , increased appetite (8.8% versus 2.3%), urticaria (11.8% versus 6.8%) and hypertriglyceridaemia (2.9% versus 0%) were reported more often for mirtazapine-treated patients than by placebo-treated patients ITT analysis: state ITT using LOCF was used  
Statistical methods: not stated |
| Selective reporting (reporting bias)          | High risk  | Only 1 outcome reported in MHRA report; Rapporteurs report gives safety outcomes in addition |
| Other bias                                    | High risk  | Contact: weekly visits (week 5 and 7 optional); psychotherapy could not be started during the trial, but ‘supportive care’ as defined in the protocol was permitted  
Screening: unclear  
Placebo lead-in: no  
Baseline imbalance: data not reported  
States it was initially 2 trials that were amalgamated a few months after trial initiation |

- Power calculation: not stated
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes
- Intervention integrity: yes - "Plasma samples, for the purpose of measuring mirtazapine, (Org 3770) concentrations, were to be collected on trial Days 28 and 56 (or the subject's final day of treatment)". Pg 4. Company trial report
- Outcome measures described or validated measures used: yes
- Follow-up assessment points: post intervention
- No. crossed over: none
- Funded by: Organon International

#### Participants

- Setting of care: outpatients
- Recruitment: through clinical practice of investigators, referrals and/or advertisements for volunteers
- Mean age (SD): intervention = 11.9; control = 12.3
- Age range: 8 to 18 years
- Gender (F:M): intervention = 46:42; control: 24:21
- Methods used to diagnose: DSM-IV diagnosis confirmed by K-SADS-L and baseline score of ≥ 15 on 1st 17 items of HAM-D (21 item), a CGAS score of < 70; CDRS-R ≥ 40; screening period not stated
- Diagnosis: MDD
- Baseline severity of depression: CDRS-R mean (SD) score: intervention = 48.87; control = 47.57
- Length of current episode: not stated
- % first episode: not stated
- Co-morbidity (intervention): not stated
- Co-morbidity (control): not stated
- Location: USA
- Inclusion criteria: current episode of MDD (as defined by DSM-IV criteria, with a primary diagnosis of major depressive disorder on the Kiddie-SADS P-L (Kiddie schedule for affective disorders and schizophrenia - present and lifetime).
Baseline score of >15 on the 1st 17 items of the Hamilton Scale for Depression, 21 items (HAM-D 21), <70 on the Children's Global Assessment Scale (C-GAS), and a Children's Depression Rating Scale-Revised (CDRS-R) score of ≥ 40
Exclusion criteria: serious suicide attempt during the current major depressive episode, or any previous suicide attempt resulting in hospitalisation; concurrent psychiatric diagnosis of anorexia or bulimia, past history of eating disorder, concurrent diagnosis of obsessive compulsive disorder or schizophrenia, bipolar disorder (I or II) or parental history of bipolar I disorder

### Interventions

**Intervention group**
- **Drug:** mirtazapine
- **Dosage:** 15 to 45 mg
- **Regimen:** starting dose 15 mg with increase to 30 to 45 mg in 15 mg increments during subsequent weeks (to 28 days)
- **Length of treatment:** 8 weeks
- **Control group:** placebo pill

### Outcomes

**Definition and assessment of response:** not stated
**Depressive symptoms:** CDRS-R clinician rating; HAM-D 21 self rating
**Functioning:** C-GAS used but no report of data
**Suicidal behaviours:** events reported as adverse events; no report of continuous measure
**Adverse events**
**Other measures:** Clinical Global Impressions (CGI), Self Report Childhood Anxiety Related Disorder (SCARED), Connors' Global Index (Parent and Teacher Versions)

### Notes

placebo: 45 total: 133  
Number of withdrawals: mirtazapine: 19; placebo: 8; total: 27  
Number analysed post intervention: mirtazapine: 83; placebo: 41; total: 124  
Reasons for drop out: MHRA reports drops across the 2 mirtazapine trials: 9 (5.3%) patients discontinued due to an adverse event in the mirtazapine group compared with 3 (3.4%) in the placebo-treated group. The most common adverse treated event leading to discontinuation in the acute phase in the mirtazapine treated group was weight gain.  
Weight gain (31.8% versus 3.4%), somnolence (38.8% versus 6.8%), headache (35% versus 23%), fatigue (19.4% versus 11.4%) , increased appetite (8.8% versus 2.3%), urticaria (11.8% versus 6.8%) and hypertriglyceridaemia (2.9% versus 0%) were reported more often for mirtazapine-treated patients than by placebo-treated patients  
ITT analysis: states ITT done using LOCF but table of participants shows ITT analysis did not include all randomised patients  
Statistical methods: not stated

| States it was initially 2 trials that were amalgamated a few months after trial initiation |
### Paroxetine Trial 1

#### Methods
- **Trial design:** randomised controlled trial; multi-site
- **Power calculation:** yes
- **Use of diagnostic criteria (or clear specification of inclusion criteria):** yes
- **Intervention integrity:** yes. Plasma concentration monitored.
- **Outcome measures described or validated measures used:** yes
- **Follow-up assessment points:** post-intervention
- **No. crossed over:** none
- **Funded by:** GSK

#### Participants
- **Setting of care:** unclear
- **Recruitment:** not stated
- **Mean age:** intervention = 14.4 years (SD = 1.99); placebo = 14.8 years (SD = 2.62)
- **Age range:** 7 to 17 years
- **Gender (F:M):** intervention = 18:9; placebo = 16:13; total female = 34, male = 22
- **Methods used to diagnose:** DSM-IV; CDRS-R score of $\geq 45$
- **Diagnosis:** MDD
- **Baseline severity of depression:** CDRS-R mean (SD) intervention = 55.4 (7.3); placebo = 56.8 (8.46)
- **Length of current episode:** not stated
- **% first episode:** not stated
- **Co-morbidity:** not stated
- **Location:** Japan
- **Inclusion criteria:** single episode of MDD or recurrent symptoms of depression or depressed state
- **Exclusion criteria:** primary diagnosis of an axis 1 disorder other than MDD, those with a history of psychotic episode or psychotic disorder or bipolar disorder
- **Exclusion of suicidality:** not stated

#### Interventions
- **Intervention group**
  - **Drug:** paroxetine
  - **Dosage:** 10 to 40 mg dependent on age
  - **Regimen:** 10 mg for 2 weeks and 10 to 20 mg for next 6 weeks for 7 to 11 year olds and 10 to 40 mg for the next 6 weeks for 12 to 17 year olds. The dose described at week 6 was maintained for the last 2 weeks
- **Length of treatment:** 8 weeks
- **Control group:** placebo pill

#### Outcomes
- **Definition and assessment of response:** Clinical Global Impressions (CGI) of 1 or 2
- **Depressive symptoms:** Change from baseline CDRS-R
- **Functioning:** no report of measure used
- **Suicidal Behaviours:** events reported as adverse events; no report of continuous data
- **Other:** Change from baseline CGI score; Incidence of adverse events

#### Notes
- **Type of data used for remission/response:** last observation carried forward

## Simeon 1990

### Methods
- **Trial design**: randomised controlled trial; single site
- **Power calculation**: not stated
- **Use of diagnostic criteria (or clear specification of inclusion criteria)**: yes
- **Intervention integrity**: yes - assessed by clinical chemistry profile
- **Outcome measures described or validated measures used**: yes
- **Follow-up assessment points**: weekly visits, post intervention and long-term follow-up on average 24 months post trial termination
- **No. crossed over**: none
- **Funded by**: not stated

### Participants
- **Setting of care**: outpatient
- **Recruitment**: no information
- **Mean age**: 16 (group ages not stated)
- **Age range**: actual range not stated
- **Gender (total)**: female = 22; male = 18 (group gender not stated)
- **Methods used to diagnose**: DSM-III criteria with HAM-D score of ≥ 20, 1-week placebo run-in period
- **Diagnosis**: MDD
- **Baseline severity of depression**: not stated for either group
- **Length of current episode**: not stated
- **% first episode**: not stated
- **Co-morbidity**: not stated for either group
- **Location**: Canada
- **Inclusion criteria**: 13 to 18 years; MDD with a HAM-D score > 20, a Raskin Depression Scale score of > 8, a Raskin Depression Score that must exceed the Covi Anxiety Scale Score, an outpatient
- **Exclusion criteria**: history of seizures, schizophrenia or other psychotic illnesses, girls who were sexually active and not using medically accepted means of contraception, patients with a recent drug or alcohol abuse
- **Exclusion of suicidality**: serious suicidal risk (no further definition)

### Interventions
- **Intervention group**
  - **Drug**: fluoxetine
  - **Dosage**: 20 to 60 mg
  - **Regimen**: initial dose 20 mg daily increased to 40 mg after 4 to 7 days, and up to 60 mg in the second week
  - **Length of treatment**: 7 weeks
  - **Control group**: placebo pill

### Outcomes
- **Definition and assessment of response**: not stated
- **Depressive symptoms**: HAM-D; Raskin Depression Scale;
- **Functioning**: no report
- **Suicidal behaviours**: no report of events or continuous measure
- **Other**: Clinical Global Impressions Scale (CGI); Covi Anxiety Scale; Hopkins Symptom Checklist
- **Follow-up assessment included semi-structured interviews by a nurse to obtain treatment subsequent to the trial, current activities and functioning with family and peers, and follow-up interview with parents using the HAM-D, Raskin, Covi and a DSM-III
checklist for MDD and an adaptive functioning scale

**Notes**

Letter requesting additional data sent. Data have not been received.

**Newer generation antidepressants for depressive disorders in children and adolescents (Review)**

Copyright © 2012 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
### TADS 2004

**Methods**
- Trial design: randomised controlled trial; multicentre
- Power calculation: yes
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes
- Intervention integrity: not described for fluoxetine and placebo arms
- Outcome measures described or validated measures used: yes
- Follow-up assessment points: post intervention
- No. crossed over: none
- Funded by: NIMH

**Participants**
- Setting of care: outpatient
- Recruitment: included newspaper, TV and radio advertising
- Mean age (total): 14.6 (SD 1.5)
- Age range (actual): 12 to 18 years
- Gender (F:M): 239:200
- Methods used to diagnose: DSM-IV confirmed using K-SADS-PL and a CDRS-R score of ≥ 45; assessment (not interview) at consent and baseline
- Diagnosis: MDD
- Baseline severity of depression: CDRS-R raw mean (SD) score: intervention: 58.96 (10.16) (T-score 74.73 (6.74)); control: 61.11 (10.50) (T-score 76.14 (6.11)); CGI intervention 4.66; CGI placebo 4.84
- Length of current episode: (median weeks) intervention 38 weeks; placebo: 35.5 weeks
- % first episode: 86% of total (not reported by group)
- Co-morbidity (intervention): any 47; dysthymia 6; anxiety 26; OCD/tic 2; ADHD 13; substance use 3; disruptive behaviour 25
- Co-morbidity (control): any 57; dysthymia 12; anxiety 28; OCD/tic 4; ADHD 19; substance use 0; disruptive behaviour 28
- Location: USA
- Inclusion criteria: outpatient; age 12 to 17; Full Scale IQ > 80; antidepressant-free before trial
- Exclusion criteria: bipolar disorder; severe Conduct Disorder; substance abuse; pervasive developmental disorder; thought disorder; use of psychotropic medication or psychotherapy (stable stimulants permitted for ADHD); 2 previous failed SSRI trials or a failed trial of CBT; confounding medical condition; non English speaking
- Exclusion of suicidality: suicidality or homocidality (patients were excluded for dangerousness to self or others if they had been hospitalised for dangerousness within 3 months of consent or were deemed by a cross-site panel to be “high risk” because of a suicide attempt requiring medical attention within 6 months, clear intent or an active plan to commit suicide, or suicidal ideation with a disorganized family unable to guarantee adequate safety monitoring)

**Interventions**
- Intervention group
- Drug: fluoxetine
- Dosage: 20 to 40 mg
- Regimen: 10 mg daily to start; increase to 20 mg daily in week 1 with increase to a...
maximum of 40 mg daily thereafter
Length of treatment: 12 weeks
Control group: placebo
Comparison group 1: CBT
Comparison group 2: CBT plus fluoxetine

Outcomes
Definition of response and assessment: we used remission CDRS-R \( \leq 28 \) (they used a range of outcomes including response and remission, using different definitions: In the main results paper they use response defined as a CGI improvement of 1 or 2)
Depressive symptoms: Children's Depression Rating Scale - Revised (CDRS-R)
Functioning: C - GAS
Suicidal behaviours: report of events based on Columbia classification; continuous measure using the Suicidal Ideation Questionnaire-Junior High School Version (SIQ-Jr)
Adverse events
Other outcomes: Clinical Global Impressions Scale Improvement (CGI-Improvement); Reynolds Adolescent Depression Scale (RADS)

Notes
Additional trial information was sought and received from the author. Data in the MA from the paper.
All young people in the trial were included as adolescents
Type of data used for remission/response: last observation carried forward

Incomplete outcome data (attrition bias)

<table>
<thead>
<tr>
<th>All outcomes</th>
<th>Low risk</th>
</tr>
</thead>
</table>
| Number eligible: 1088  
Number randomised: fluoxetine: 109; placebo: 112; total: 439 (including additional 2 trial arms)  
Number started trial: fluoxetine: 109; placebo: 112; total: 439 (including additional 2 trial arms)  
Number of withdrawals: fluoxetine: 18; placebo: 23; total: 90 (including additional 2 trial arms)  
Number analysed post intervention: fluoxetine: 109; placebo: 112; total: 439 (including additional 2 trial arms)  
Reasons for drop out: full table of number of drop outs and reason for drop outs given pg 811. Reasons for drop out are not specific e.g. terminated prematurely. Similar reasons in each group except 10 participants in the placebo group withdrew consent, compared with 5 in the fluoxetine group  
ITT analysis: "all analyses were conducted using an intent-to-treat analysis"; "primary intent to treat, all patients regardless of treatment status return for all scheduled assessments" pg 535 in the 2003 publication  
Statistical methods: for the CDRS -R results linear random coefficient regression model; used random-effects for participants and clinical site (but site interaction omitted). Responder (CGI-I) used logistic regression model for last available assessment point (LOCF) with site as covariate | Number of participants blind to treatment assignment. Specific instructions were provided to parents, participants and the independent evaluator not to disclose treatment assignment" pg 808 in the 2004 publication  

Selective reporting (reporting bias)

| High risk |
| Percentage given for CGI-I response rates. Multiple publications report varying outcome results that are not consistent across papers. In the 2004 paper presenting the main results, functioning was not reported |

Other bias

| Unclear risk |
| Contact: "Patients have one pharmacotherapist throughout the trial who, in addition to monitoring clinical status and medica- |
### TADS 2004 (Continued)

| Effect sizes | Offers general encouragement about the effectiveness of pharmacotherapy for MDD. Major assessments undertaken at baseline, 12 weeks, 24 weeks and 36 weeks with minor assessments at 6 weeks, 18 weeks and 30 weeks. 2003 publication pg 537. "six 20 to 30 minute medication visits spread across 12 weeks of treatment” 2004 publication pg 809.
| Baseline imbalance: no. Baseline imbalance: for main results paper (2004) there were none reported; no demographic information given by group; Table 1 reports baseline clinical information with no significant differences reported across the four treatment groups.
| TADS 2005 paper on demographics does not report demographic and clinical characteristics by group.

### Von Knorring 2006

| Methods | Trial design: randomised controlled trial; multicentre. Power calculation: not stated. Use of diagnostic criteria (or clear specification of inclusion criteria): yes. Intervention integrity: yes - non compliance assessed by blood levels of citalopram. Outcome measures described or validated measures used: yes. Follow-up assessment points: post intervention. Funded by: pharmaceutical company not stated.
| Participants | Setting of care: in and outpatient (14% of participants hospitalised at entry to trial). Recruitment: no information. Mean age (SD): 16 (1). Age range: 13 to 18 years. Gender: not stated. Methods used to diagnose: DSM-IV including 5-minute interview with parents. Global assessment of functioning less than 60 on either symptoms, activities, relationships or personal care, BDI less than 21 for girls and less than 16 for boys. Diagnosis: MDD. Baseline severity of depression: K-SADS-P intervention 32.5; control = 32.3 and totals only for MADRS 30 (SD = 5/6), GAF 55 (SD = 7); CGI not reported. Length of current episode: not reported. % first episode: intervention 72%; placebo 64%. Co-morbidity: not stated for either group.
Location: Denmark, Estonia, Finland, Germany, Norway, Sweden, Switzerland
Inclusion criteria: DSM-IV MDD current episode of greater than 4 weeks but less than 1 year duration; in or outpatient plus score of at least 21 or 16 on BDI and at least 60 on the GAF; 13 to 18 years inclusive; Tanner Stage III (commencement of puberty)
Exclusion criteria: bipolar disorder including hypermania; ongoing DSM-IV Attention Deficit Disorder or disruptive behaviour disorder; DSM-IV psychotic disorder; progressive neurological disorder; drug or alcohol abuse that influences daily functioning; primary anorexia nervosa or bulimia nervosa; attends special school for mentally retarded; pervasive developmental disorders
Exclusion of suicidality: not explicitly stated

</tbody>
</table>
| Incomplete outcome data (attrition bias) | High risk | Number eligible: not stated  
Number randomised: citalopram: 124; placebo: 120; total: 244  
Number started trial: citalopram: 121; placebo: 112; total: 233  
Number of withdrawals: citalopram: 45; placebo: 46; total: 91  
Number analysed post intervention: citalopram: 121; placebo: 112; total: 233  
Reasons for drop out: full table of number of drop outs but full description of reasons for drop outs not given. More withdrew from the placebo group due to lack of efficacy and more withdrew from the citalopram group due to adverse effects  
ITT analysis: efficacy analyses were conducted on an intent-to-treat population, which included all randomised patients who took at least 1 dose of double-blind medication and who had at least 1 valid post assessment kiddie-SADs-P assessment pg 312  
Statistical methods: primary analysis based on adjusted mean change of observed case data using ANCOVA. Dichotomous data analysed using LOCF |
| Selective reporting (reporting bias) | High risk | Error in the von Knorring paper when describing response data where it is reported twice and both times as OC data. Both response and remission data are only reported as percentages and when calculating these out using both the ITT population and the OC population the whole numbers do not match. Results only (no data) are reported for functioning, depression severity (clinician and self rated) |
| Other bias | Unclear risk | Contact: evaluation undertaken at 1, 2, 5, 9 and 12 weeks. Psychotherapy was allowed and three-quarters of the participants received it  
Screening: there was 1 screening visit and then a baseline visit |
Placebo lead-in: no
Baseline imbalance: authors state that baseline data were similar for the 2 treatment groups, however, much baseline data (e.g. depression severity, age) was not reported by group. There were more patients in the citalopram group hospitalised for a psychiatric disorder and with a first episode
Other: after recruitment of 15% of the population the trialists changed the inclusion criteria to ≥16 on the BDI for boys and added the MADRS. Post hoc analysis of high versus low baseline scores and of those receiving psychotherapy versus not receiving psychotherapy

Wagner 2004

Methods
- Trial design: randomised controlled trial; multicentre
- Power calculation: not reported
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes
- Intervention integrity: not described
- Outcome measures described or validated measures used: yes
- Follow-up assessment points: post intervention
- No. crossed over: none
- Funded by: Forest Pharmaceuticals

Participants
- Setting of care: outpatients
- Recruitment: no information
- Mean age (SD): Intervention = 12.1 (2.8); control = 12.1 (3.1)
- Age range: 7 to 17 years
- Gender (F:M): intervention = 54:39; control = 43:42
- Methods used to diagnose: DSM-IV confirmed using The Schedule for Affective Disorders and Schizophrenia for School-Age Children-Present and Lifetime Version (K-SADS-P and L) and a CDRS-R score of ≥40
- Diagnosis: MDD
- Baseline severity of depression: CDRS-R mean (SD) score: intervention = 58.8 (10.9); control = 57.8 (11.1); CGI not reported
- Length of current episode: (mean months) intervention: 20.8 (21.4); placebo: 18.6 (16.4)
- % first episode: intervention 78.7%; placebo 82.4%
- Co-morbidity (intervention): dysthymia 5; enuresis 4; previous ADHD 4
- Co-morbidity (control): dysthymia 1; enuresis 3; previous ADHD 1
- Location: USA
- Inclusion criteria: MDD of at least 4 weeks' duration; normal physical exam, laboratory tests and Electrocardiography (ECG); parent available to accompany child
- Exclusion criteria: primary psychiatric diagnosis other than MDD; ADHD; PTSD; bipolar disorder; pervasive developmental disorder; mental retardation; CD; ODD; any
psychotic features; any personality disorder that would interfere with treatment; alcohol or substance abuse; anorexia or bulimia nervosa; initiation of psychotherapy or behaviour therapy 3 months prior to trial entry; and antidepressant or anxiolytic medication in 2 weeks prior to trial entry; neuroleptic or stimulant medication within 6 months of trial entry
Exclusion of suicidality: suicide risk or previous active attempt in previous year or hospitalised due to attempt

Incomplete outcome data (attrition bias) & High risk & Number eligible: 178  
Number randomised: citalopram: 93; placebo: 85; total: 178  
Number started trial: citalopram: 93; placebo: 85; total: 178  
Number of withdrawals: citalopram: 4; placebo: 0; total: 36  
Number analysed post intervention: citalopram: 89; placebo: 85; total: 174  
Reasons for drop out: 4 patients all randomly assigned to citalopram group were lost to follow-up and did not receive trial medication. “These patients were not included in the Intention-to-Treat (ITT) analysis”...of these (ITT population) 18 patients from each group discontinued double-blind treatment prematurely pg 1080. Reasons for drop out are not described  
ITT analysis: “These (4 patients in the citalopram group who were lost to follow-up) patients were not included in the Intention-to-Treat (ITT) analysis”...of these (ITT population)  
Statistical methods: analysis of covariance with treatment, trial centre, and age as factors and baseline scores as covariate. Cochrane-Mantel Haenszel test controlling for centre and age group. Used LOCF  

Selective reporting (reporting bias) & High risk & Percentages only given for response data. Response in this trial is defined in the same way as remission is defined in many other SSRI trials (TADS, Emslie 1997 and 2002 Emslie 2006) but remission itself is not included as an outcome in this trial. Depression symptom severity means and standard deviations were not reported but represented in a figure with a result only reported (MHRA report change scores)  

Other bias & Unclear risk & Contact: evaluation undertaken at 1, 2, 4, 6 and 8 weeks. Psychotherapy was not allowed pg 1080  
Screening: there was 1 screening visit and then a baseline visit  
Placebo lead-in: 1 week single-blind in between screening visit and baseline visit  
Baseline imbalance: authors report no sig-

Number analysed post intervention: escitalopram: 129; placebo: 132; total: 261 |
Reasons for drop out: full list of drop outs and reasons for drop out figure 1 pg 283. Trial authors state no significant differences in specific reasons for premature discontinuation; appear to be more withdrawing consent from escitalopram group. ITT analysis: efficacy analyses were performed on the intent-to-treat population, which included all patients in the safety population (i.e. received at least 1 dose of trial medication) who had at least 1 post-baseline CDRS-R assessment pg 282. Statistical methods: LOCF was used (as well as some OC analysis). Analysis of covariance (treatment group and trial centre as factors and baseline scores as covariate). Logistic regression with treatment as the factor and baseline scores as covariate pg 282.

Selective reporting (reporting bias) | Unclear risk | 2 prospective definitions of response were used. A post hoc analysis of suicide-related outcomes was undertaken (pg 282). Only P values are provided for clinician-rated depression symptoms.

Other bias | Low risk | Contact: evaluations at end of 1, 2, 4, 6 and 8 weeks; psychotherapy was not allowed (pg 281). Screening: diagnostic criteria have to be met at the screening visit and then again at the baseline visit after the 1-week placebo lead-in. Baseline imbalance: authors state there were no significant differences between the groups. Other: not noted.

some weekly data and they looked at individual items in their measures. While the paper does not report on remission as an outcome the MHRA report does have these data by group. Response data are given as percentages in the paper and these data do not match MHRA data. Denominators for response and remission in the MHRA data are different. They do not report total adverse event rate.

Other bias | High risk  
Contact: authors state there were “frequent follow-up visits” pg 1039 and regular measurements taken. They were also allowed to receive therapy pg 1035  
Screening: diagnostic criteria have to be met at the first and third visits during a 2-week screening period (total of 3 visits in the screening period)  
Placebo lead-in: no  
Baseline imbalance: authors state there were no differences between the groups except for gender (more females than males)  
Other: this is mostly a first episode population; there were 2 studies reported in the one paper; trial 2 had much higher response and remission rates, but data are not reported separately in the published paper.

Wagner Trial 1 (2003)

Methods  
Trial design: randomised controlled trial; multicentre  
Power calculation: yes  
Use of diagnostic criteria (or clear specification of inclusion criteria): yes  
Intervention integrity: not described  
Outcome measures described or validated measures used: yes  
Follow-up assessment points: post intervention  
No. crossed over: none  
Funded by: Pfizer

Participants  
Setting of care: outpatient  
Recruitment: no information  
Mean age: not stated for either group  
Age range: 6 to 17 years  
Gender (F:M): intervention = 108:81; control = 84:103  
Methods used to diagnose: DSM-IV confirmed using K-SADS-PL, a CDRS-R score of \( \geq 45 \) and a CGI-S score of \( \geq 4 \)  
During 2-week screen had to meet these criteria at first and third visit  
Diagnosis: MDD  
Baseline severity of depression: CDRS-R mean (SD) score intervention = 64.3 (11.0); control = 64.6 (11.0); CGI intervention 4.6 (0.6); CGI placebo 4.5 (0.7)
### Length of current episode: not reported

% first episode: intervention 95%; placebo 95%

Co-morbidity (intervention and control): 40% of participants had at least 1 co-morbid condition; the conditions that occurred in at least 5% of patients included anxiety; phobic disorder; adjustment reaction; ODD

Location: USA, India, Canada, Costa Rica, Mexico

Inclusion criteria: outpatients; aged 6 to 17; MDD at the first and third visits during a 2-week screen and current episode had to be of at least 6 weeks duration; illness of at least moderate severity

Exclusion criteria: Attention Deficit Hyperactivity Disorder; Conduct Disorder; Obsessive Compulsive Disorder; panic disorder; history of bipolar or current psychotic features; history of psychotic disorders or autistic spectrum disorders; current anorexia nervosa or bulimia nervosa; drug or alcohol abuse/dependence within 6 months or current positive drug screen; pregnant or breast feeding; abnormal Electrocardiography (ECG), laboratory test results, vital signs or body weight; current use of other psychotropic medication; intention to commence psychotherapy; requirement of concomitant psychotropic therapy; previous failed response to an SSRI; additionally trial 2 stated it excluded those requiring inpatient admission

Exclusion of suicidality: previous suicide attempt or current significant suicidal or homicidal risk

### Interventions

**Intervention group**

Drug: sertraline

Dosage: flexible dosage 25 to 200 mg

Regimen: 25 mg for 3 days; 50 mg till the end of the second week; increases as indicated by 50 mg per day to a maximum of 200 mg

Length of treatment: 10 weeks

**Control group:** placebo pill

### Outcomes

Definition and assessment of response: we used OC remission: subjects who no longer met DSM-IV criteria for a current major depression episode at endpoint from MHRA (they used responders defined as at least 40% decrease on Children's Depression Rating Scale - Revised (CDRS-R))

Depression symptoms: Childrens Depression Rating Scale (CDRS-R)

Functioning: Childrens Global Assessment Scale (C-GAS)

Suicidal behaviour: events reported as adverse events; no report of continuous outcome

Other outcomes:

Clinical Global Impressions Scale Severity (CGI-Severity); Clinical Global Impressions Scale Improvement (CGI - Improvement); clinician-rated severity; Multidimensional Anxiety Scale for Children (MASC); Pediatric Quality of Life Enjoyment and Satisfaction Questionnaire (PQ-LES-Q); adverse events

### Notes

Additional data were sought from authors. No response was received.

MHRA contacted for additional data for #1001 and 1017, some of which were provided MHRA data used in MA as it gave data for each separate trial and separately for child and adolescent

Type of data used for remission/response: last observation carried forward

| **Methods**         | Trial design: randomised controlled trial  
Power calculation: not stated  
Use of diagnostic criteria (or clear specification of inclusion criteria): yes  
Intervention integrity: NA  
Outcome measures described or validated measures used: yes  
Follow-up assessment points: 10 weeks; 36 weeks  
No. crossed over: none  
Funded by: Eli Lily |
| **Participants**    | Setting of care: outpatient  
Recruitment: not stated  
Mean age: NA  
Age range: 7 to 17 years  
Gender (F:M): NA  
Methods used to diagnose: DSM-IV TR confirmed using MINI-KID; CDRS-R ≥ 45 and CGI ≥ 4  
Diagnosis: MDD  
Baseline severity of depression: NA  
Co-morbidity intervention and control: NA  
Location: USA, Canada, Mexico  
Inclusion criteria: moderate or greater severity of MDD as determined by CDRS-R ≥ 40 at screen, and randomisation and a CGI-Severity rating ≥ 4 at screen, and randomisation  
Exclusion criteria: current or previous diagnosis of bipolar disorder, psychotic depression, schizophrenia or other psychotic disorder, anorexia, bulimia, obsessive compulsive disorder, or pervasive development disorder, as judged by the investigator; history of DSM-IV-TR-defined substance abuse or dependence within the past year; current primary DSM-IV-TR Axis I disorder other than MDD or a current secondary DSM-IV-TR Axis I disorder that requires any pharmacologic treatment; 1 or more first-degree relatives with diagnosed bipolar I disorder; significant suicide attempt within 1 year of screening or are currently at risk of suicide in the opinion of the investigator; significant suicide attempt within 1 year of screening or are currently at risk of suicide in the opinion of the investigator |
| **Interventions**   | Intervention group  
Drug: duloxetine  
Dosage: 30 to 120 mg  
Regimen: once daily  
Length of treatment: 36 weeks  
Control group: placebo  
Comparison group: fluoxetine 10 to 40 mg  
Evaluations at baseline, 10 weeks, 36 weeks |

### Solvay NCT00353028

<table>
<thead>
<tr>
<th>Trial name or title</th>
<th>Solvay NCT00353028</th>
</tr>
</thead>
</table>

#### Methods
- Trial design: randomised controlled trial; multicentre
- Power calculation: not stated
- Use of diagnostic criteria (or clear specification of inclusion criteria): yes
- Intervention integrity: NA
- Outcome measures described or validated measures used: yes
- Follow-up assessment points: 8 weeks
- No. crossed over: not stated
- Funded by: Solvay Pharmaceuticals

#### Participants
- Setting of care: not stated
- Recruitment: not stated
- Mean age: not stated
- Age range: 8 to 18 years
- Gender (F:M): NA
- Methods used to diagnose: the Japanese Version of the Structured Interview Guide for the Hamilton Depression Rating Scale (JSIGH-D) 17-item total score
- Diagnosis: depression or depressive state
- Baseline severity of depression: not stated
- Co-morbidity intervention and control: NA
- Location: Japan
- Inclusion criteria: a minimum total score of 18 on the JSIGH-D, weight within the standard weight ± 2 SD based on the standard weight for each age in the School Health Statistical Survey
- Exclusion criteria: predominant psychiatric diagnosis - schizophrenia, or previously been treated with fluvoxamine maleate

#### Interventions
- Intervention group:
  - Drug arm 1: fluvoxamine maleate
  - Dosage: 25 mg to 150 mg (1 to 6 tablets)
  - Regimen: once daily
  - Length of treatment: 8 weeks
- Control group: placebo
- Evaluations at baseline, 8 weeks

#### Outcomes
- Depressive symptoms: time of onset of 50% decrease from baseline in the JSIGH-D
- Functioning: the Clinical Global Impression scale (CGI)

#### Starting date

#### Contact information
| Notes | Contacted Toshiaki Yamaguchi, trial director at Solvay Pharmaceuticals on 13 October 2011 regarding trial status, however no reply received at time of publication |

CDRS-R: Children's Depression Rating Scale - Revised; CGI: Clinical Global Impressions Scale; DSM-IV-TR: Diagnostic and Statistical Manual of Mental Disorders IV - Text Revision; K-SADS: Schedule for Affective Disorders and Schizophrenia for School Aged Children; JSIGH-D: Japanese Version of the Structured Interview Guide for the Hamilton Depression Rating Scale; MDD: major depressive disorder; NA: not applicable; OC: observed case; SD: standard deviation
## DATA AND ANALYSES

Comparison 1. Newer generation antidepressant versus placebo (by drug)

CONTRIBUTIONS OF AUTHORS

Sarah Hetrick
Conceived the review.
Co-ordinated preparation of the protocol and the review.
Contributed to the search strategy, extraction of information about the trials and outcome data, 'Risk of bias' assessment, data analysis and preparation of the text of the review.

Jo McKenzie
Assisted with the assessment of risk of bias of the included trials. Advised on the analysis of the data and made a significant contribution to writing the results, including input to the discussion and conclusions.

Georgina Cox
Extracted data, double entered data, updated tables of included studies and additional tables, assisted the write-up of some of the results, and reviewed the final manuscript.
Magenta Simmons
Screened studies for inclusion and exclusion, updated the background section, assisted with the discussion and reviewed the final manuscript for the updated version of the review.

Sally Merry
Help to conceive the review.
Provided general advice on the protocol.
Helped prepare the text of the review, with a significant contribution to the discussion and conclusion of the review.

Per Sindahl
Provided general advice on the protocol. Contributed to extraction of information about the trials and outcome data, and preparation of the text of the review for the first published version of the review. He was unable to contribute to the update of the review.

Michelle Proctor
Assisted with preparation of the protocol and made significant contribution to running the search strategy, contributed to extraction of information about the trials and outcome data, and commented on the text of the first published version of the review. She was unable to contribute to the update of the review.

Alison Ward
Provided with general advice on the protocol, contributed to extraction of information about the trials and outcome data and commented on the text of the review of the first published version of the review. She was unable to contribute to the update of the review.

DECLARATIONS OF INTEREST
Per Sindahl works at Leo Pharma A/S, however, his main areas are dermatology and critical care. He is not involved in psychiatric disorders.

There is no conflict of interest for any author.

SOURCES OF SUPPORT

Internal sources
- Colonial Foundation, Australia.
Orygen Youth Health Research Centre receives funds from the Colonial Foundation
- Australian National Health and Medical Research Council (NHMRC) Clinical Training Fellowship, Australia.
Person support for Sarah Hetrick for research focused on implementation of evidence for youth depression
**External sources**
- No sources of support supplied

**DIFFERENCES BETWEEN PROTOCOL AND REVIEW**

Inclusion criteria have changed for this version of the review and now include all 'second and third' or newer antidepressant compounds. Additionally, sub-syndromal depression was not included.

We have added as an objective the aim to look at effectiveness by drug type; this analysis was undertaken in the first review but not explicitly described in the objectives.

Analysis has been reorganised such that there is not a separate meta-analysis for each antidepressant compound, rather, these have become one of two subgroup analyses.

**NOTES**

The results for the two duloxetine studies became available in July 2012, just as the review was being finalised for publication. The results for these studies will be incorporated in an update of this review in early 2013.

**INDEX TERMS**

**Medical Subject Headings (MeSH)**

Antidepressive Agents [adverse effects; *therapeutic use]; Citalopram [administration & dosage; therapeutic use]; Depressive Disorder [*drug therapy; psychology]; Fluoxetine [adverse effects; therapeutic use]; Induction Chemotherapy; Paroxetine [adverse effects; therapeutic use]; Randomized Controlled Trials as Topic; Serotonin Uptake Inhibitors [adverse effects; *therapeutic use]; Sertraline [administration & dosage; therapeutic use]; Suicide [*psychology]
